TUNE UP

ENGINE TUNE-UP has become increasingly important to the modern automotive engine with its vastly improved power and performance. With the higher compression ratios, improved electrical systems and other advances in design, engines have become more sensitive to usage and operating conditions, all of which have a decided effect on power and performance. It is important, therefore, that this service be performed on the engine every spring and fall or more often if conditions warrant.

Compression Test

The engine cannot be tuned to develop maximum power and smooth performance unless reasonably high and uniform compression pressure is obtained in each cylinder. The compression in each cylinder should, therefore, be tested before any other tune-up operations are performed.

1. Remove any foreign matter from around spark plugs by blowing out plug area with compressed air. Then loosen all plugs one turn.
2. Start engine and accelerate to a fast idle to blow out loosened carbon. Stop engine and remove spark plugs. *Cleaning out carbon in this manner is important in preventing false compression readings due to particles of carbon lodged under the valves.*
3. Remove air cleaner and block throttle and choke in wide open position.
4. Insert compression gauge firmly in spark plug opening and crank engine through at least four or five compression strokes to obtain highest possible reading.
5. Test and record compression of each cylinder. Compression should read within the limits given in the *Tune Up Charts* in truck chapters. The variation between highest and lowest reading should be less than 20 pounds.
6. If one or more cylinders read low, inject about a tablespoon of engine oil on top of pistons in the low reading cylinders. Crank engine several times and recheck compression.
7. If compression comes up but does not reach normal it indicates worn piston rings. If compression does not improve, valves are sticking or seating poorly. If two adjacent cylinders indicate low compression and injecting oil does not improve the condition, the cause may be a head gasket leak between the cylinders.

Cylinder Balance Test

It is sometimes difficult to locate a weak cylinder especially in an eight cylinder engine. A compression test, for example, will not locate a leaky intake manifold, a valve not opening properly due to a worn camshaft, or a defective spark plug.

With the cylinder balance test, the power output of one cylinder may be checked against another, using a set of grounding leads, Fig. 1. When the power of each cylinder is not equal, the engine will lose power and run roughly. The cylinder balance test is as follows:

Fig. 1 Cylinder balance test connections. The firing order in this example is 1-8-4-3-6-5-7-2. Therefore, the cylinders to be tested together are 1-6, 8-5, 4-7, 3-2, using the grounding leads as shown

1. Connect a tachometer and vacuum gauge.
2. Start engine and run it at a fast idle.
3. Ground large clip of grounding leads and connect individual leads to all spark plugs *except the pair being tested* (see Fig. 1).
4. Divide the firing order in half and write down the first half over the second half. The cylinders to be tested together appear one over the other:

Firing Order	Pairs Tested
1-8-4-3-6-5-7-2	1-6, 8-5, 4-7, 3-2
1-2-7-8-4-5-6-3	1-4, 2-5, 7-6, 8-3
1-5-4-8-6-3-7-2	1-6, 5-3, 4-7, 8-2
1-5-4-2-6-3-7-8	1-6, 5-3, 4-7, 2-8
1-8-7-3-6-5-4-2	1-6, 8-5, 7-4, 3-2
1-6-5-4-3-2	1-4, 6-3, 5-2
1-5-3-6-2-4	1-6, 5-2, 3-4
1-4-5-2-3-6	1-2, 4-3, 5-6
1-3-4-2	1-4, 3-2

5. Operate engine on each pair of cylinders in turn and note engine rpm and manifold vacuum for each pair. A variation of more than one inch of vacuum or 40 rpm between pairs of cylinders being tested indicates that the cylinders are off balance.
6. To isolate one weak cylinder, short out one bank of cylinders at a time. The bank giving the lower readings will include the weak cylinder.

Spark Plugs

1. Examine firing ends of plugs for evidence of oil fouling, gas fouling, burned or overheated condition. *Oil fouling is usually identified by wet, sludgy deposits caused by excessive oil consumption. Gas fouling is identified by dry, black, fluffy deposits caused by incomplete combustion. Burned or overheated spark plugs are identified by white, burned or blistered insulator nose and badly burned electrodes. Improper fuel, insufficient cooling or improper ignition timing normally are the cause. Normal conditions are usually identified by white powdery deposits or rusty-brown to grayish-tan powdery deposits.*
2. Clean plugs with a suitable sand blast cleaner following the manufacturer's instructions.
3. Remove carbon and other deposits from threads with a stiff wire brush.
4. Dress electrodes with a small file to secure flat, parallel surfaces on both center and side electrodes, Fig. 2.
5. Use a round wire gauge to check the gap, Fig. 3, and adjust by bending the side (never center) electrode to the proper specifications as shown in the *Tune Up Charts* in truck chapters.
6. If gaskets are used, place new ones on plugs and torque them to the specifications given in the *Engine Tightening Specifications* chart in truck chapters.

Service Notes

Improper installation of spark plugs is one of the greatest single causes of unsatisfactory spark plug performance. Improper installation is the result of one or more of the following practices: 1) Installation of plugs with insufficient torque to fully seat the gasket; 2) excessive torque which changes gap settings; 3) installation of plugs on dirty gasket seal; 4) installation of plugs to corroded spark plug hole threads.

Failure to install plugs properly will cause them to operate at excessively high temperatures and result in reduced operating life under mild operation or complete destruction under severe operation where the intense heat cannot be dissipated rapidly enough.

Always remove carbon deposits in hole threads before installing plugs. When corrosion is present in threads, normal torque is not sufficient to compress the plug gasket (if used) and early failure from overheating will result.

Always use a new gasket (if required)

and wipe seats in head clean. The gasket must be fully compressed on clean seats to complete heat transfer and provide a gas tight seal in the cylinder. For this reason as well as the necessity of maintaining correct plug gap, the use of correct torque is extremely important during installation.

Ignition System Service

1. Replace brittle or damaged spark plug wires. Install all wires to proper spark plug. The *Tune Up Charts* in truck chapters give firing orders should wires become mixed.
2. Tighten all ignition system connections.
3. Replace or repair any wires that are frayed, loose or damaged, Fig. 4.
4. Remove distributor cap, clean and inspect for cracks, carbon tracks and burned or corroded terminals. Replace cap if necessary.
5. Clean rotor and inspect for damage or deterioration. Replace rotor if necessary.
6. Check distributor centrifugal advance mechanism (if used) by turning distributor rotor in direction of running rotation as far as possible, then release rotor to see if springs return it to its retarded position. If rotor does not return readily, the distributor must be disassembled and cause of trouble corrected.
7. Check to see that the vacuum spark control operates freely by turning the movable breaker plate (if used) or distributor housing in a direction opposite to that of running rotation to see if the spring returns it to the retarded position. Any stiffness in the operation of the spark control will affect ignition timing. Correct any interference or binding condition noted.
8. Examine distributor points and clean or replace if necessary. Points with an overall gray color and only slight roughness or pitting need not be replaced.
9. Dirty points should be cleaned with a clean point file. Use only a few strokes of the file. The file should not be used on other metals and should not be allowed to become dirty or greasy. *Never use emery cloth or sandpaper to clean points since particles will embed and cause arcing and rapid burning of points.* Do not attempt to remove all roughness nor dress the point surfaces down smooth. Merely remove scale or dirt.
10. Replace points that are badly burned or pitted. Where burned or badly pitted points are encountered, the ignition system and engine should be checked to determine the cause of the trouble so it can be eliminated. Unless the condition causing point burning is corrected, new points will provide no better service than the old points. See *Ignition* chapter for an analysis of point burning or pitting, and for proper installation of points.

Fig. 2 Spark plug details

Battery & Cables

Inspect for signs of corrosion on battery, cables and surrounding area, loose or broken carriers, cracked or bulged cases, dirt and acid, electrolyte leakage and low electrolyte level. Fill cells to proper level with distilled water or water passed through a "demineralizer".

Fig. 3 Correct and incorrect spark plug gauges

Fig. 4 What to look for when checking for high resistance in the primary circuit of distributor. In addition to the points indicated, look for external circuit high resistance at ignition switch terminals, ammeter terminals, coil terminals and broken or poorly insulated wires in this circuit

The top of the battery should be clean and the battery hold-down bolts properly tightened. Particular care should be taken to see that the tops of 12-volt batteries are kept clean of acid film and dirt because of the high voltage between the battery terminals.

For best results when cleaning batteries, wash first with a dilute ammonia or soda solution to neutralize any acid present and then flush off with clean water. Care must be taken to keep vent plugs tight so that the neutralizing solution does not enter the battery. The hold-down bolts should be kept tight enough to prevent the battery from shaking around in its holder, but not so tight that the battery case will be placed under a severe strain.

To insure good contact, the battery cables should be tight on the battery posts. Oil battery terminal felt washer. If the battery posts or cable terminals are corroded, the cables should be cleaned separately with a soda solution and a wire brush. After cleaning and before installing the clamps, apply a thin coating of vaseline to the posts and cable clamps to help retard corrosion.

If the battery has remained undercharged, check for a loose generator belt, defective generator, high resistance in charging circuit, oxidized voltage regulator contact points, or a low voltage setting.

If the battery has been using too much water, the voltage regulator setting is too high.

Fan Belt & Generator

1. Inspect fan belt condition and check adjustment.
2. Inspect generator commutator and brushes for cleanliness or wear. The commutator should be cleaned if dirty and brushes should be replaced if worn down to less than half their original length. *The commutator may be cleaned by holding a strip of No. 00 sandpaper or a cleaning stone against it while the generator is operating.*
3. Replace or repair frayed or broken generator wires and tighten all wire connections.
4. Lubricate generator by filling hinge cap oilers with light engine oil.

Ignition Timing

The use of a timing light, Fig. 5, is recommended for checking and setting ignition timing. Timing that is set back as much as six degrees from the best setting will definitely decrease acceleration and top speed performance.

Fig. 5 Checking ignition timing with timing light

CARBURETION

Since carburetion is dependent in several ways on both compression and ignition, it should always be checked last when tuning an engine. See the vehicle chapter for adjustments for the unit you are interested in.

Before adjusting the carburetor, consider the factors outlined below and which definitely affect engine performance.

Carburetor Flange

Check the flange for looseness on the manifold. If one of the flange nuts is loose as little as one-half turn, a sufficient amount of air will enter the intake manifold below the throttle plate to destroy engine idle and all engine performance.

If a tight fit cannot be obtained by tightening the nuts, install a new gasket but be sure that all the old gasket material has been removed.

Throttle Linkage

If the throttle linkage is adjusted so that the accelerator pedal will strike the floor board before the throttle plate is wide open, it will result in low top speed.

Fuel Lines

A restriction of the fuel line will result in an apparent vapor lock action or a definite cut-off of gasoline. This can generally be corrected by blowing out the line with compressed air. In some cases, it may be necessary to replace the line.

Fuel Pump

The pump should be tested to make sure that it will draw an adequate supply of fuel from the tank and deliver it to the carburetor under all conditions of operation. If the pump functions inefficiently, proper adjustment and operation of the carburetor is impossible because the fuel will not be maintained at the prescribed level in the idle passages and main discharge jet (or jets) of the carburetor under all operating conditions.

Fuel Tank

The fuel tank should not be overlooked as a possible source of trouble with carburetion. A shortage of fuel at the fuel pump or carburetor may be caused by pieces of filling station pump hose or other material obstructing the mouth of the feed pipe in the tank, or by a restriction of the air vents in the filler cap and neck.

An unusual amount of dirt, water or gum in the fuel filter indicates that the tank is contaminated with these substances, which should be cleaned out to prevent future failure of the pump or carburetor.

Heat Control Valve

The heat control valve performs an important function in carburetion during the warm-up period, Fig. 6. Carbon or rust formation around the shaft may cause the valve to stick or become sluggish in operation.

A valve sticking in the open position will cause slow engine warm-up, excessive spitting and sluggish engine operation when cold. A valve sticking in the closed position will cause overheating, loss of power and hard starting when the engine is hot, and may also cause warped or cracked manifolds. Sticking in either position will adversely affect fuel economy.

Grasp the counterweight and rotate the valve through its entire range. The valve must rotate freely and the shaft must have a slight end play. If the shaft is frozen in the manifold, free it up by gently tapping on the ends with a light hammer, and by rotating the counterweight at the same time.

Lubricate the shaft with a thin mixture of powdered graphite and alcohol or kerosene while moving the counterweight back and forth to work the lubricant into the bearings. Do not use oil as this will form carbon and cause sticking of the valve.

Inspect the thermostat and the anti-rattle spring to make sure they are properly assembled.

Intake Manifold Leaks

Leakage of air into the intake manifold at any point will affect carburetion and general engine performance. Air may leak into the manifold through the joints at the carburetor or cylinder head, cracks in the manifold, cracks or poor connections in the windshield wiper or windshield washer hose lines, or the connections of any accessories which may be connected to the manifold. All such joints should be tested for leaks.

To test the intake manifold for leaks, apply oil from an oil can along the gasket joints with the engine idling. An air leak is indicated when oil is drawn past the gaskets by the suction of the engine. Tighten the nuts or cap screws holding the manifold to the engine and retest for leaks. If tightening fails to stop the leaks, replace the manifold gaskets. If the new gaskets fail to stop the leaks, carefully inspect the manifold for cracks and test any suspicious area with oil.

Air Cleaner

An air cleaner with a dirty element, or with oil that is dirty, too heavy, or too high in the sump, will restrict the air flow through the carburetor and cause a rich mixture at high speeds. In such a condition the air cleaner likewise will not properly remove dirt from the air, and the dirt entering the engine will cause rapid formation of carbon, sticking valves, and wear of piston rings and cylinder bores.

Automatic Choke

The choke mechanism must be inspected and cleaned to make sure it is operating freely. Sluggish action or sticking of the choke will cause excessive fuel consumption, poor performance during warm-up and possibly hard starting.

The choke thermostat should be set in accordance with the average air temperature as well as the volatility of the fuel being used. It is desirable to have the thermostat set as lean as operating conditions permit in order to avoid an over-rich mixture during engine warm-up.

PERFORMANCE TEST

After an engine has been tuned up, the truck should be given a thorough and systematic road test to make certain that engine power and performance are up to standard under all operating conditions. The gasoline used in making the test must be of good quality and proper octane rating in order to obtain the performance described in the following tests.

Fig. 6 Operation of a typical manifold heat control valve

Engine Warm Up

On vehicles with automatic chokes, a cold engine should operate on fast idle for two to five minutes, depending upon air temperature.

At 32 deg. F. the fast idle cam should move to the slow idle position in approximately ½ to ¾ mile of driving. At higher temperatures, it should move to the slow idle position in a correspondingly shorter distance.

If the engine loads excessively or runs rich on warm up due to a rich choke setting, excessive fuel consumption, carbon formation, and spark plug fouling will result.

An engine which is adjusted for smooth idling in cold outside temperature will not idle smoothly for any length of time in a warm building, since the required carburetor adjustment will cause richness of mixture in the warmer atmosphere.

Gradual Acceleration Test

Starting at idling speed in high gear, gradually open the throttle to increase smoothly the speed of the truck through the entire range. Note any roughness, flat spots, or surging in engine performance during acceleration, and the speed at which the unusual condition occurs.

Roughness or poor performance at speeds below 20 m.p.h. indicates improper carburetor idle adjustment, restriction in idle passages in carburetor, tight valve lash or sticking valves, or faulty ignition.

Faulty ignition usually causes a more pronounced roughness than imperfect compression or carburetion.

Roughness or poor performance at speeds above 20 m.p.h. indicates restriction or improper settings in the high speed circuit of the carburetor, or faulty ignition.

Wide Open Throttle Acceleration Test

With the truck running at idling speed in high gear, quickly press the accelerator pedal to the floor and hold it there, meanwhile noting the performance of the engine as the vehicle is accelerated. Repeat the acceleration test, starting at different constant speeds throughout speed range of the vehicle. The truck should accelerate smoothly without hesitation, spitting, or loading of the engine.

A hesitation, spitting, or a flat spot indicates that the accelerating pump is not discharging sufficient gasoline into the engine. Sluggishness or loading indicates that the accelerating pump is adjusted too rich.

Constant Speed Test

Hold the truck speed constant at various points through the speed range and note engine performance. The engine should operate smoothly without hesitation or surging under load at all constant speeds.

At some point between 15 and 22 m.p.h. with the truck rolling along on a level road or slight upgrade, a slight leanness, surging or missing may be detected. Depressing or releasing the accelerator pedal slightly will eliminate this condition and no attempt should be made to correct it by altering carburetion or ignition. This condition seldom appears in the normal operation of the vehicle.

Spark Knock

Light detonation or spark knock will occur when operating with part throttle on a hard pull, even though the ignition is properly timed and Ethyl or other high octane fuel is used. Light detonation also will occur when accelerating with fully opened throttle on a hard pull. These operating conditions are normal and no attempt should be made to eliminate light detonation by retarding the ignition timing.

If regular or low octane fuel is used, detonation will probably be excessive with the standard ignition timing, and it may be necessary to retard the timing, which will reduce fuel economy and over-all performance.

Extreme heavy detonation is injurious to any engine. A truck driven continuously under conditions and fuels which produce heavy detonation will overheat and lose power, with the possibility of damage to pistons and bearings.

Valve Noise

With the valves adjusted uniformly to specifications, the noise level should be very low as observed in the vehicle while driving. The sound of valve action should be audible, however, when the hood is raised or when the engine is operating on fast idle during warm up.

The valve lash should not be reduced below specifications in an attempt to eliminate valve noise, as this will cause premature valve failure and rough engine performance, especially at idle.

Sticking valves usually are indicated

Fig. 7 Schematic drawing showing how either the road draft or manifold suction systems of crankcase ventilation operate

by an intermittent loudness of action, although the valves will be unusually noisy at all times if they are sticking badly. Sticking valves will cause irregular operation or missing on a low speed pull.

Noisy Hydraulic Lifters

The easiest method of locating a noisy valve lifter is by the use of a piece of garden hose about 4 feet in length. Place the end of the hose near the end of each intake and exhaust valve with the other end of the hose near the ear. In this manner, the sound is localized, making it easy to tell which lifter is at fault.

Another method is to place a finger on the face of the valve spring retainer. If the lifter is not functioning properly, a distinct shock will be felt when the valve returns to its seat.

In most cases where noise exists in one or more lifters, all lifter units should be removed and cleaned. If dirt, varnish, carbon, etc., is found to exist in one unit, it more than likely exists in all the units.

Plungers are not interchangeable as they are selectively fitted at the factory. Should a plunger or lifter body become damaged, it is necessary to replace the entire unit.

CRANKCASE VENTILATION

Crankcase ventilation has an important function in controlling sludge and keeping the engine lubricating system in good condition. Ineffective or inoperative crankcase ventilators are responsible for lubricating troubles serious enough in some cases to cause engine failure.

Two methods of crankcase ventilation are in use, the road-draft system and manifold vacuum system, both shown schematically in the same drawing in Fig. 7.

Fig. 8 shows a typical road draft type. As indicated by the direction of the arrows, air is driven into the crankcase by fan draft through a copper gauze filter in the oil filler cap. It then circulates around the inside of the engine and is discharged through the ventilator outlet pipe, carrying with it the water vapor which collects in the crankcase, particularly in cold weather. Whenever the oiling system is cleaned, the filler and outlet pipes should be removed and flushed out thoroughly. The gauze filters should also be washed in clean gasoline or kerosene.

In order to control smog, the manifold vacuum system of crankcase ventilation is standard equipment on 1961-62 cars to be used in California and is mandatory on all cars starting with 1963 models. The correct operation of this system depends upon a free flow of air from the carburetor air cleaner through the oil filler tube and engine to the control valve mounted on the intake manifold, Fig. 7. The arrows indicate the direction of the flow of air.

The system sucks crankcase vapors into the intake manifold to be burned in the combustion chamber. The flow of the vapors is controlled by the ventilator valve. The valve is actuated by engine vacuum working against spring tension. The high vacuum at engine idle provides minimum ventilation; low vacuum at road speeds provides maximum vacuum.

Servicing the system consists of checking the valve, the tubing and the air intake. The valve should be removed and checked for proper operation and for harmful deposits. If necessary, disassemble the valve, clean the parts in solvent and dry with compressed air. Inspect each component carefully. If the spring is distorted or the valve is worn the valve should be replaced. When reassembling the valve, make sure the end coil of the spring is snapped into the groove which is usually just under the head of the valve.

Fig. 8 Road draft system of crankcase ventilation

Remove the tubing and blow out any deposits with compressed air. When reinstalling the valve and tubing, make sure all connections are tight to prevent air leaks.

On some engines, the system air intake is a hose from the air cleaner to the oil filler tube. Make sure the hose is in good condition, and all connections are air tight. Check the oil filler tube cap to be sure it makes an air tight seal on the tube. Air leaks can easily be checked for by squirting kerosene at the connections.

On other engines, the system air intake is a filter type oil filler tube cap. Check the cap filter to be sure it is free of dirt. Clean it in solvent if necessary.

If the control valve becomes clogged with carbon or other foreign matter the ventilation system will not operate and a slight pressure will build up in the crankcase which may cause oil leakage at the rear main bearing or by the piston rings. And should the valve fail to seat it will be impossible to make the engine idle satisfactorily.

IGNITION DISTRIBUTORS

THE ignition system can be divided as follows, Fig 1.

1. Battery to supply current.
2. Ignition wiring to carry current to the units in the system.
3. Ignition switch to control the circuit.
4. Ignition coil to increase the voltage delivered to the spark plugs.
5. A distributor to distribute current to each cylinder.
6. Spark plugs to ignite the fuel in each cylinder.

But inasmuch as the "Tune Up" chapter deals with such service as comes within the province of tuning up an engine—such as batteries, spark plugs, etc.—this chapter will discuss the functions and service requirements of the distributor itself, together with any additional data not included in the "Tune Up" chapter.

Fig. 1 Typical ignition system

BREAKER CONTACT POINTS

Contact Analysis

The normal color of points should be a light gray. If the contact surfaces are black it is usually caused by oil vapor or grease from the cam. If they are blue, the cause is usually excessive heating due to improper alignment, high resistance or open condenser circuit.

If the contacts develop a crater or depression on one point and a high spot of metal on the other, the cause is an electrolytic action transferring metal from one contact to the other, Fig. 2. This can be the result of some unusual operation of the vehicle. A slow-speed driver in city traffic or door-to-door delivery vehicles will be one extreme, and high-speed, long distance driving would be the other extreme. It may also be due to an unbalanced ignition system, which can sometimes be improved by a slight change in condenser capacity. If the mound is on the positive point, Fig. 3, install a condenser of greater capacity; if on the negative point, Fig. 4, use a condenser of lesser capacity.

One of the most common causes of point failure is the presence of oil or grease on the contact surfaces, usually from over-lubrication of the wick at the top of the cam or too much grease on the rubbing block of the breaker arm.

Breaker Point Gap

Correct contact point opening is important, especially during starting and low speed operation. If points are set too close, arcing and burning will occur, causing hard starting and poor low speed performance. If points are set too wide, the cam angle or dwell will be too small to allow saturation of the coil at high engine speeds, resulting in weak spark.

Contact point opening has a direct bearing on cam angle or dwell which is the number of degrees that the breaker cam rotates from the time the points close until they open again, Fig. 5. The cam angle or dwell increases as point opening is decreased and vice versa. In view of the importance of point opening to low speed engine performance and cam dwell to high speed engine performance, the cam angle or dwell should be checked after adjusting and aligning points. This is done on a distributor testing machine, following the manufacturers instructions.

Breaker Arm Spring Tension

Breaker arm spring tension is important. If the tension is too great the arm will bounce, causing an interruption of the current in the coil and misfiring. If the spring tension is too little, the rubbing block will not follow the cam, causing a variation in cam dwell. The spring tension should always be set at the high

Fig. 2 Showing how metal from one contact transfers to the other

Fig. 3 Mound on positive point

Fig. 4 Mound on negative point

Fig. 5 Cam angle or dwell

Fig. 6 Measuring breaker arm spring tension

Fig. 7 Breaker point alignment

Fig. 8 Dial indicator for measuring breaker gap

Fig. 9 Why flat feeler gauge will not provide accurate point spacing if points are rough

limit as given in the *Distributor Specifications* chart in truck chapter, as it will be reduced as the rubbing block wears.

Hook a spring scale on the breaker arm and pull in a straight line as shown in Fig. 6. Take a reading as the points start to separate under the slow and steady pull of the scale. If the tension is not within specification, loosen the screw that holds the end of the point spring and slide the end of the spring in or out as necessary. Tighten the screw and recheck the spring tension.

Breaker Point Alignment

Check alignment of points with points closed, Fig. 7. Align new points where necessary but do not attempt to align used points. Instead, replace used points where serious misalignment is observed. After aligning points, adjust point gap.

Adjusting Breaker Gap

Specifications for breaker gap, *as measured with a wire gauge,* is listed in the *Tune Up Specifications* in truck chapters. However, if at all possible, this opening should be set on a distributor testing machine or with a dial indicator, Fig. 8. This not only eliminates the possibility of an incorrect gap setting but if the points are slightly rough but otherwise in alignment, there is the danger of obtaining an incorrect gap, as shown in Fig. 9.

The advantage of a distributor testing machine is that it not only measures cam angle or dwell but it also uncovers irregularities between cam lobes, point bounce, alignment of rubbing block with cam, alignment of contacts and breaker arm spring tension.

Setting Auto-Lite Dual Points

The distributor used on some Chrysler Corp. cars contain two sets of points which permit additional current build-up in the primary winding of the coil, Fig. 10. Thus, maximum voltage is induced in the secondary winding.

The two sets of points are connected in parallel and are positioned in relation to the 8-lobe cam so as to provide a 7-degree overlap of points opening and closing. One set of points (circuit *maker* points) closes the primary circuit in the coil and the second set of points (circuit *breaker* points) opens the circuit, causing a spark at the plug. Immediately after the spark occurs, the circuit *maker* points are closed ahead of the circuit *breaker* points, thus providing a circuit to build-up the primary winding. As the cam rotates further, the secondary points close and just before the secondary points open, the primary points open 7 degrees ahead.

Since the "make" and "break" points are timed to close and open at the exact instant necessary for efficient engine operation, adjustment of the points is an important factor in correct distributor operation.

Feeler Gauge or Dial Indicator Method—Rotate the distributor shaft until the breaker arm rubbing block of one set of points is on the high spot of the cam. Then, with a screwdriver blade in the triangular opening, close or open the points to the proper clearance by turning the screwdriver blade against the stationary point plate. Check the clearance with a clean wire gauge or dial indicator. Then turn the distributor shaft until the rubbing block of the second set of points is on the high spot of the cam and adjust the second set of points in the same manner

Dwell Meter Method—If this method is used *block one set of points open* with a piece of wrapping paper or calling card. Then adjust the other set of points to the correct dwell angle. Now block open the first set of points and adjust the second set. After both sets of points have been adjusted, allow them to operate together while checking that their total dwell angle measures up to manufacturer's specifications.

Auto-Lite & Chrysler Single Point Set Adjustment

Adjustment of breaker gap is accomplished by loosening the lock screw in the stationary point and moving the adjusting screw as required to obtain the correct breaker gap.

Delco-Remy Internal Adjustment Breaker Points

For distributors used starting with 1962 Corvair, an opening in the point set assembly allows for easy dwell angle or breaker point adjustment, Figs. 11 and 12.

For the early type, prior to 1956, the adjustment is accomplished by loosening the lock screw from the stationary contact and moving the adjusting screw as required to obtain the proper adjustment.

Delco-Remy External Adjustment Breaker Points

With engine running at idle speed, the

Fig. 10 Auto-Lite dual point distributor

Fig. 11 Adjusting breaker gap or cam dwell on Corvair 1960-61 distributor

breaker gap is adjusted by first raising the window provided in the cap and inserting a "hex" wrench into the adjusting screw, Fig. 13. Turn the adjusting screw clockwise until the engine begins to misfire. Then give the wrench one-half turn in the opposite direction which will provide the proper breaker gap. If a cam angle meter is to be used, turn the adjusting screw until the correct angle is obtained.

Holley Breaker Points

The breaker point set is attached to the movable breaker plate. A slot in the stationary point bracket allows for easy breaker point adjustment, Fig. 14.

CONDENSER

A condenser should not be condemned because the points are burned or oxidized. Oil vapor, or grease from the cam, or high resistance may be the cause of such a condition.

Condensers should be tested with a good condenser tester for leakage, breakdown, capacity, and resistance in series in the condenser circuit. Manufacturers of condenser testers furnish complete instructions as to their use.

IGNITION COIL

If poor ignition performance is obtained and the coil is suspected, it may be tested on the car or it may be removed for the test.

Ignition coils are often condemned when the trouble is actually in the ignition switch. A completely defective ignition switch will produce an open primary circuit, giving the same indications as if the coil were completely dead. A partly defective ignition switch will cause a weak spark. Both of these conditions are often blamed on the coil.

By cutting the ignition switch out of the circuit, it can easily be determined whether or not the coil is defective or whether fault lies with ignition switch.

In the absence of any testing equipment a simple check of an ignition coil can be made as follows: Turn on ignition switch with breaker points closed. Remove the high tension cable from the center socket of the distributor cap and hold it ¼ to ⅜" away from a clean spot on the engine. Then open and close the points with a screwdriver. If the coil and other units connected to it are in good condition a spark should jump from the wire to the engine. If not, use a

Fig. 12 Breaker point setting. 1962-63 Corvair

Fig. 13 Adjusting breaker point gap through window in distributor cap

Fig. 14 Breaker plate details. Holley Loadamatic distributor. Note slot for adjusting breaker gap

Fig. 15 Wiring connections for coil with negative grounded system

Fig. 16 Wiring connections for coil with positive grounded system

jumper wire from the primary terminal of the distributor to the engine; if the primary is in good condition a spark will occur.

All ignition coils with metal containers can be tested for grounded windings by placing one test clip on a clean part of the metal container and touching the other clip to the primary and high tension terminals. If the lamp lights or tiny sparks appear at the points of contact, the windings are grounded and the coil should be replaced.

Coil Polarity

Most coils are marked positive and negative at the primary terminals. When installing or connecting a coil, be sure to make the connections as shown in Figs. 15 and 16.

If perchance the coil is not marked as to its polarity, it can be checked by holding any high tension wire about ¼" away from its spark plug terminal with the engine running. Insert the point of a wooden lead pencil between the spark plug and the wire, Fig. 17. If the spark flares and has a slight orange tinge on the spark plug side of the pencil, polarity is correct. If the spark flares on the cable side, coil connections should be reversed.

Fig. 17 Checking coil polarity

IGNITION RESISTORS

The ignition coils used with 12-volt systems are specially designed *6-volt coils* which operate with a resistor connected in series with the primary ignition circuit. The purpose of the resistor is to prolong the service life of the distributor breaker points.

In the Auto-Lite system the resistor consists of an ordinary resistance wire that is sensitive to temperature. It has a lower resistance value when cold than when hot. When the ignition is first turned on, more current will flow through the primary windings of the coil for a very short time until the resistor heats up.

In the Delco-Remy and Ford systems, the resistor is of the constant temperature type; that is, it is not affected by temperature and its resistance is approximately the same when cold and when hot. However, in this system a feature is employed which shorts out the resistor while the engine is being cranked by the starter and automatically puts the resistor back into the coil circuit as soon as the starter switch is released. This is accomplished by by-passing the resistor through the starter solenoid. The solenoid has an additional terminal from which a wire runs directly to the coil. The resistor is by-passed by means of a "finger" inside the switch housing which is attached to the additional switch terminal.

Under no circumstances should a 12-volt system be operated with the resistor shorted out as the breaker points will burn up in short order. What happens is that 12 volts will be placed across the 6-volt coil and this will double the normal current through the breaker points.

Unlike the methods illustrated in Fig. 18, the resistance used on some vehicles starting in 1960 consists of a high resistance wire incorporated in the instrument panel wiring harness. The wire used with the Delco-Remy systems is stainless steel, plastic coated and covered with a glass braid. A similar wire is used on Ford vehicles.

The four 12-volt coil and resistor setups in use are shown in the wiring diagrams, Fig. 18.

No. 1 circuit shows a 12-volt coil without any resistor in the primary circuit. The primary winding, however, has a high resistance value.

No. 2 circuit shows the most common Delco-Remy type. It has an external resistor which does not change with temperature. The primary winding of the coil is similar to that of a 6-volt coil but it has a higher resistance value. Note that in this set-up the ignition circuit is wired so that the external resistor is shorted out while the starter switch is operating.

No. 3 circuit is the most common Auto-Lite type. It uses an external resistor whose resistance value changes with temperature. When the car is being started, the cold resistor permits a higher current through the coil primary, resulting in easy starting. As the resistor warms up, its resistance increases to cut down the primary current through the coil for normal operation.

No. 4 circuit shows an Auto-Lite coil with the resistor incorporated within the coil housing.

CENTRIFUGAL ADVANCE

Except for Holley "full vacuum" distributors, all other distributors utilize an automatic advance mechanism which functions by virtue of centrifugal weights. Some distributors employ both centrifugal and vacuum advance mechanisms, while others make use of only the centrifugal mechanism.

When engine speed increases, the spark must be introduced in the cylinder earlier in the cycle in order that the fuel charge can be ignited and will have time to burn and deliver its power to the piston. To provide this spark advance based on engine speed, the centrifugal governor mechanism is used.

This mechanism, Fig. 19, consists of centrifugal advance weights which throw out against spring tension as the engine speed increases. This movement imparts, through a toggle arrangement, rotational motion to the breaker cam, causing it to rotate a number of degrees with respect to the distributor drive shaft. This causes the lobes on the cam to close and open the contacts earlier in the cycle so that the spark is induced and is delivered to the cylinder earlier with respect to the position of the upward moving piston.

In servicing the distributor, all weights should be removed from the hinge pins, cleaned and checked for excessive wear, either in the weights or pins, or the plate which is slotted for the movement of the pins on top of the governor weights. Replacement should be made if there is any appreciable wear in the slots, as any wear at this point would change the characteristic of the spark advance.

If these parts are in good condition, the hinge pins should be lubricated before being reassembled, by greasing the hinge pins and filling the pockets in the governor weights with grease. Do not use vaseline for this purpose as its melting point is comparatively low.

When installing new centrifugal governor assemblies, it is important that the spacer washers between the housing and shaft be installed correctly. If incorrectly installed, the governor assembly will be too high, causing it to rub against the bottom of the breaker plate.

On some distributors, both springs are alike, while on others there is one heavy and one light spring, as in Fig. 19. Another combination that may be found is an additional flat spring on the outside of the outer spring posts, Fig. 20. As the governor speed is increased, the flat springs are first pulled against the posts by the eyes of the coil springs to provide a rapid spark advance of a few degrees before the coil springs pull against the spring posts.

Fig. 18 Wiring diagrams of 12-volt coil and resistor circuits

Fig. 19 Top view of Delco-Remy distributor with breaker plate removed to show centrifugal advance mechanism

VACUUM ADVANCE

The two types of vacuum advance mechanisms used on Auto-Lite and Delco-Remy distributors are illustrated in Figs. 21 and 22. Both types make use of a spring-loaded diaphragm which is connected through linkage to the distributor. The spring loaded side of the dia-

Fig. 20 Flat spring used on some governors to provide a rapid spark advance

Fig. 21 Auto-Lite vacuum advance mechanism of type mounted on side of distributor. Breaker plate is supported on a ball bearing, and the breaker plate alone rotates in the housing as vacuum conditions change

Fig. 22 Auto-Lite vacuum advance mechanism of type clamped around distributor so that entire distributor is rotated as vacuum conditions change

phragm is air tight and is connected through a vacuum line to the carburetor above the throttle plate so that idling performance will not be affected.

When the throttle is open vacuum from the intake manifold is introduced into the vacuum advance mechanism and the diaphragm is pulled against the spring causing the distributor to advance.

In Fig. 21 the mechanism is attached to the distributor breaker plate so that the breaker plate rotates. In Fig. 22, the mechanism is connected to the distributor body so that the entire distributor moves. In both cases, the rotational movement carries the contact points around to an advanced position so that the breaker cam closes and opens the points earlier in the cycle.

See Holley Distributor Service for vacuum advance data for these units.

Auto-Lite IBP Distributors

Used on some late model Dodge trucks, this distributor uses a very different type vacuum spark advance. Unlike other systems which either rotate the breaker plate or the entire distributor when manifold vacuum is high, the IBP breaker plate is pivoted in such a way that the points swing in an arc about the cam when the vacuum advance unit is in operation. Thus, cam angle and breaker point gap change as high manifold vacuum advances the spark. For this reason cam angle should be checked with the vacuum line disconnected and the point gap checked or adjusted when the vacuum advance unit is in full retard position.

AUTO-LITE & CHRYSLER DISTRIBUTOR SERVICE

If the distributor has been disassembled, reassemble as follows, referring to Figs. 23 and 24 for guidance.

1. Check operation of centrifugal weights and weight springs for distortion. Lubricate governor weights.
2. Inspect all bearing surfaces and pivot pins for roughness, binding, or excessive looseness.
3. Install cam spacer (chamfered end down) on distributor shaft.
4. Slide cam and yoke on distributor shaft. Engage weight lugs with slots in yoke as shown in Fig. 25. Install cam retaining clip, being sure it is properly seated in distributor shaft groove.
5. Lubricate and install two concave washers for Auto-Lite distributors or a single flat thrust washer for Chrysler distributors. Position washers on shaft and slide shaft into distributor body.
6. Position lower thrust washer and drive collar on lower end of shaft and install retainer pin.
7. Install oiler wick and oiler.
8. Install breaker plate assembly, align condenser lead, breaker point spring, primary lead and install attaching screw.
9. Install felt wick in top of distributor cam.
10. Attach vacuum advance unit arm to breaker plate and install retainer. Install vacuum unit attaching screws and washers.
11. Test breaker arm spring tension and adjust breaker gap.
12. Lubricate felt pad in top of distributor cam with 3 to 5 drops of light engine oil and install rotor.

DELCO-REMY DISTRIBUTOR SERVICE

Internal Adjustment Type

Fig. 26 shows an exploded view of a typical distributor of this type. Due to its similarity to the Auto-Lite unit, use the Auto-Lite procedure as a guide when assembling this unit.

External Adjustment Type

If the distributor has been disassem-

Fig. 23 Disassembled view of a typical Autolite distributor

Fig. 24 Disassembled view of a typical Chrysler Corp. distributor

bled, refer to Fig. 27 for guidance when reassembling.

1. Place gasket on shaft housing.
2. Place felt washer around bushing in housing.
3. Install vacuum advance unit.
4. Install breaker plate in housing and spring retainer on upper bushing.
5. Install condenser.
6. Install breaker point set.
7. Install cam and weight base assembly on shaft. If lubrication in grooves at top of shaft was removed during disassembly, replace with Plastilube #2 or its equivalent.
8. Install shaft and cam weight assembly in housing.
9. Using a pin, install driven gear to shaft.
10. Install advance weights and springs.
11. Install cam lubricator
12. Install rotor.
13. Check breaker arm spring tension and adjust breaker gap.

Corvair 1960-61 Distributor

This distributor, Fig. 28, has the breaker plate located below the centrifugal advance mechanism and uses the outer diameter of the shaft bushing for its bearing surface. The position of the vacuum control unit when mounted on the distributor housing determines the location of the breaker plate. Note the calibrated scale stamped on top of the breaker plate, Fig. 29. To correctly position the breaker plate during assembly at the factory a mark on the calibrated scale is located opposite the edge of the slot in the distributor housing. This position should not be changed unless there is evidence that the plate has been moved from its original setting.

If the distributor has been disassembled, refer to Fig. 28 for guidance when reassembling.

1. Install felt washer around bushing in housing.
2. Install vacuum unit but do not tighten hold-down screws at this time.
3. Install breaker plate in housing and spring retainer on upper bushing.

Fig. 26 Disassembled view of a typical Delco-Remy internal adjustment distributor

Fig. 25 Distributor shaft details

Fig. 27 Delco-Remy external adjustment distributor

Fig. 28 Delco-Remy distributor used on Corvair 1960-61

4. Position breaker plate with 23° mark in line with scribe mark on housing, Fig. 29, and tighten vacuum unit hold-down screws.
5. Install breaker points.
6. Install condenser.
7. Install cam and weight base assembly on shaft. If lubrication in grooves at top of shaft was removed during disassembly, replace with Plastilube #2 or equivalent.
8. Install shaft and cam weight assembly in housing.
9. Slide thrust washers and gear on shaft and secure with pins.
10. Install advance weights and springs.
11. Install rotor.
12. Adjust breaker arm spring tension and breaker points.

Corvair 1962-63 Distributor

If the distributor has been disassembled, reassemble it as follows. Fig. 30 shows the details of the breaker plate and attaching parts.

1. Replace cam assembly to shaft. Lubricate top end of shaft with light engine oil prior to replacing.
2. Install weights on their pivot pins. Install weights, weight cover and stop plate.
3. Lubricate shaft and install in housing.
4. Install thrust washers and driven gear to shaft and secure with roll pins. Check to see that shaft turns freely. Install driven gear with mark on hub in line with rotor segment.
5. Install breaker plate.
6. Attach condenser and breaker point set in proper location with appropriate attaching screws, Fig. 30.

Fig. 29 Corvair 1960-61 distributor showing calibrated scale stamped on top of breaker plate

Connect primary and condenser leads to breaker point set quick disconnect terminal. *Contact point set pilot must engage matching hole in breaker plate.*

7. Attach vacuum control assembly to distributor housing, using upper mounting holes.
8. Adjust breaker arm spring tension and breaker gap.
9. Install rotor.

D-R EXTERNAL ADJUSTMENT TYPE DISTRIBUTOR WITH BUILT-IN SPEED GOVERNOR

Except for the built-in maximum speed governor, Fig. 31, this distributor is similar to the standard external adjustment type.

Fig. 30 Breaker plate installation. 1962-63 Corvair

Fig. 31 Delco-Remy distributor speed governor mechanism

The governor mechanism, encased in a chamber in the distributor housing, is assembled on and revolves with the distributor shaft. Disassembly, assembly and adjustment of the governor mechanism is made through external openings in the casting that are covered with a removable cover band.

The governor assembly consists of a valve shaft extending through the distributor main shaft. One end of the shaft has a slotted head, whereas the opposite end is threaded to take the adjusting nut. Assembled to the slotted head of the valve shaft is a plain washer, a ballast weight, and a rubber shock absorbing sleeve inside the weight. Assembled on the opposite end is a return spring and a self-locking adjusting nut.

Fig. 32 shows a simplified diagram of the air flow and vacuum connections between the carburetor and distributor. An air line connects the carburetor air cleaner to the governor chamber in the distributor housing. A vacuum line connects the lower opening in the distributor housing to the carburetor actuator.

When the distributor shaft revolves, the centrifugal force of the weight pulls against the spring, causing the valve shaft to move transversely in the main shaft. The slots on the valve shaft move into the main shaft of the distributor, gradually restricting the flow of air. When this restriction occurs, vacuum is created in the carburetor actuator, causing it to move the butterfly valve in the carburetor, thereby governing the engine speed. When the valve shaft in the distributor does not restrict air flow, air is brought from the air cleaner through the distributor. An overriding feature on the carburetor butterfly valve allows the foot pedal to control the butterfly valve position except when the vacuum diaphragm pull is sufficient to overcome the opposing spring force.

Governor Adjustment

The distributor governor mechanism can be adjusted off the vehicle to an approximate setting by using an approved tester and the following procedure:

1. With the "spinner" valve (centrifugal valve) adjusted so that at least two threads on the valve are showing behind the nut, mount the distributor in the tester.
2. Screw vacuum adapter into lower vacuum opening on distributor housing.

Fig. 32 Air flow and vacuum connections between carburetor and Delco-Remy governed distributor

Fig. 33 Delco-Remy twin cap distributor for V-12 engines

Fig. 34 Sectional views of Delco-Remy twin cap distributor

3. With vacuum hose pinched or bent double to prevent leakage through the hose, adjust vacuum so that gauge reads 5.0″ Hg. Release hose, then repeat adjustment until reading returns to 5.0″ Hg each time the hose is pinched.
4. Attach vacuum hose to adapter on distributor and start tester. Increase speed until vacuum reading reaches a maximum value. This maximum value will vary, depending on the type "spinner" parts used, but will probably be above 3.8″ Hg.
5. After this maximum reading has been reached, slowly decrease distributor speed until vacuum gauge pointer falls back .1″ Hg. The speed at which this .1″ Hg drop occurs will be the approximate no-load governed speed. (Bear in mind that distributor rpm is half engine rpm when making this adjustment.)
6. Final adjustment must be made with the distributor on the vehicle. Road testing is necessary for accurate full-throttle governing; however, it can be assumed that full-throttle governed speed will be about 200 rpm below no-load governed speed. Therefore, the governed speed can be checked by operating the engine at high speed in neutral.
7. To adjust distributor governing mechanisn, stop the engine, remove the cover band from the distributor and turn the centrifugal valve adjusting nut. Fig. 31, holding opposite end of shaft with a screwdriver as adjusting nut is turned.
8. To increase speed limit setting, turn adjusting nut clockwise, and vice-versa.
9. When the cover band is replaced, be sure it covers the openings and is tight so as to prevent dirt from entering the chamber.

D-R TWIN CAP DISTRIBUTOR

Used on GMC V-12 engines, this distributor, Fig. 33, is used with two ignition coils and is constructed with two sets of breaker points and two distributor caps and rotors. This means that one coil, one contact set, one cap and one rotor fire the six cylinders in one bank, whereas the other coil, contact set, cap and rotor fire the six cylinders in the other bank.

The two contact sets are actuated by a single cam on the distributor main shaft, and there are two primary lead-in wires —one for each contact set. The rotor in each distributor cap is mounted onto a *cross shaft* which is geared to the main shaft inside the distributor housing, Fig. 34.

The centrifugal advance mechanism is located on the main shaft under the breaker plate assembly. The vacuum advance unit is mounted onto the side of the main housing and is linked mechanically to the plate onto which are mounted the two contact sets.

Ignition Timing

The timing should be checked according to vehicle manufacturers recommendations. If one bank is timed correctly,

and the other bank is not correct, the two contact sets are out of position with respect to each other. To synchronize the contact sets, follow the procedure outlined below:

Contact Angle

The contact angle of each contact set can be checked with the distributor mounted either on the engine or in a test stand.

1. With the contact angle meter connected to the left bank primary lead, check the contact angle at moderate distributor speed. If adjustment is required, loosen the contact set hold-down screw and turn the eccentric screw, Fig. 35.
2. After retightening the hold-down screw, recheck the contact angle for accuracy.
3. To check the right bank contact set, connect the meter to the right bank primary lead and follow the same procedure.

Synchronizing Contact Sets

The right bank contact set is mounted on an adjustable plate. When the plate is moved, the number of degrees between point opening of the left bank and right bank contacts is changed. The plate must be adjusted so that the specified number of degrees occurs between firing of each set.

To accomplish this, mount the distributor in a test stand and check the firing difference in degrees by connecting the test stand lead alternately to each primary lead. Adjust by loosening the two hold-down screws and turning the eccentric screw of the adjustable plate.

An alternate method of checking is to observe the timing of the right bank of cylinders on the engine when the left bank is correctly timed. If the right bank is also correctly timed, the contacts are synchronized.

Fig. 35 Top view of Delco-Remy twin cap distributor (cover plate removed)

Fig. 36 Delco-Remy twin cap distributor showing cam slot alignment

Fig. 37 Delco-Remy twin cap distributor showing cross shaft slot alignment

Centrifugal & Vacuum Advance

The distributor must be mounted in a test stand to check the advance curves. It is necessary to check these curves on one contact set only.

Disassembly

Before the distributor is disassembled, it is necessary to observe the position of the rotors with respect to each other, so they can be reassembled in the same position. To do this, remove the cover plate, both caps, and turn the main shaft so the slot in the top of the shaft is aligned with the two primary lead slots in the housing, Fig. 36. Observe the position of the rotors with respect to each other, and also note that the rotor segment in the *left bank* is directly over the line marked "L" in the base, and the other rotor segment in the *right bank* is directly over the line marked "R". The slot in each cross shaft will also be aligned with the line in each base when the rotors are in this position, Fig. 37. To complete the disassembly, proceed as follows:

1. Remove both rotors, and separate each distributor cap base from main housing by removing the attaching screws.
2. Pull cross shafts from main housing.
3. Remove vacuum unit.
4. Remove breaker plate hold-down screws and lift plate out of housing.
5. Detach cover over weight base assembly and separate cam from main shaft.
6. Remove bearing hold-down plate, and gear from shaft.
7. Lift main shaft out of top of housing.

Reassembly

This procedure is the reverse of disassembly. To install the cross shafts correctly, align the main shaft slot with the two primary lead holes in the housing, Fig. 36, and install the cross shafts so the rotor segments will align directly over the proper line, Fig. 37. To obtain an accurate adjustment, loosen the two attaching screws and rotate the base so the line marking is aligned with the cross shaft slot. When the cross shaft is aligned, the rotor segment will be directly over the line marking as shown.

Fig. 38 Breaker plate installation. Holley Loadamatic distributor

Fig. 39 Disassembled view of Holley Loadamatic distributor

HOLLEY DISTRIBUTORS

Ford Loadamatic Type

With these distributors, Figs. 38 and 39, engine speed and load requirements are satisfied by the action of the breaker plate which is controlled by a vacuum-actuated diaphragm working against the tension of two calibrated breaker plate springs. The breaker plate is free to rotate on the shaft bushing.

For distributors used with six-cylinder engines, the diaphragm moves the breaker plate in a counterclockwise direction to advance the spark, and the springs move the breaker plate in a clockwise direction to retard the spark. The degree of spark advance is determined by the strength of the vacuum acting on the diaphragm. For distributors used with eight-cylinder engines, spark is advanced by the diaphragm moving the breaker plate in a clockwise direction, and retarded by the springs moving the plate in a counterclockwise direction. Six-cylinder distributors rotate clockwise, eight-cylinder units counterclockwise.

For all eight-cylinder distributors, a vacuum-actuated spark control valve is attached to the carburetor throttle body to control manifold vacuum to the distributor and regulate spark advance.

All distributors used on 1955-56 Ford, Lincoln and Mercury with four-barrel carburetor incorporate a double diaphragm for better control of breaker plate advance characteristics. The purpose of the second diaphragm is to provide a rapid spark retard at the acceleration tip-in point. The primary spark control diaphragm operates in the same manner as the single type diaphragm.

Vacuum Advance, Adjust

The two breaker plate springs are precision set at the factory with special stroboscopic equipment. This equipment is available for adjustment purposes commercially. Shops having conventional distributor testers can include a mercury column to take care of the setting of these springs as the conventional vacuum gauge will not provide the required accuracy.

Fig. 40 Spark advance adjustment on Holley Loadamatic distributor

Fig. 42 Disassembled view of Holley dual advance distributor

The spring adjusting posts shown in Fig. 40 provide the means of adjusting the spark advance.

Distributor Service

If the distributor has been disassembled, refer to Fig. 39 for guidance on reassembly.

1. Pass primary wire assembly through opening in distributor, working from inside to outside of distributor housing. Pull wire through opening until locating stop is flush with inside of distributor. Install ground wire.
2. Position breaker plate in body and secure with lock ring.
3. Position breaker point set on breaker plate, Fig. 38. Be sure pivot pin enters hole in breaker plate.
4. Connect ground wire to breaker plate at end closest to adjustment slot. Install other screw and lock washer at opposite end of assembly.
5. Install condenser.
6. Install two return springs on adjustment and breaker plate post, Fig. 40. Make sure secondary spring is adjacent to vacuum chamber.
7. Install vacuum unit.
8. Insert top of vacuum rod through breaker plate. Attach rod with retainer.
9. Slide shaft into body, using care not to damage rubbing block on breaker points.
10. Press gear on shaft. If a new shaft is being installed, place a .028" feeler in position against distributor mounting flange, press gear on shaft until it bottoms against feeler gauge. Remove feeler gauge and secure with ⅛" pin after drilling hole in shaft.
11. Install distributor cap clamps. Lubricate cam with high temperature, non-fiber grease.
12. Adjust breaker arm spring tension, align and adjust breaker points, adjust vacuum advance and cam dwell.

Holley Dual Advance Distributor

This distributor, Figs. 41 and 42, is similar to conventional design in that both a centrifugal advance mechanism is provided to regulate ignition timing according to speed and a vacuum advance unit to regulate ignition timing according to load. However, unlike other make distributors, the centrifugal advance mechanism can be adjusted through a

Fig. 41 Breaker plate installation. Holley dual advance distributor

Fig. 43 Vacuum advance adjustment. Holley dual advance distributor

Fig. 44 Adjustment of centrifugal advance

Fig. 45 Holley "Roto-Vance" (carburetor governor control) distributor

slot in the breaker plate. The vacuum advance can also be adjusted by changing the calibration washers between the vacuum chamber spring and nut, Fig. 43.

Adjust centrifugal advance before adjusting vacuum advance. If the correct advance is not indicated when tested on a distributor machine, bend one spring bracket with a screwdriver through the hole in the breaker plate, Fig. 44. Bend bracket away from distributor shaft to decrease advance and toward shaft to increase advance. Identify bracket after adjustment is made. After an adjustment has been made to one spring, check the minimum advance point again. Then operate distributor at the specified rpm to give an advance just below maximum. If this advance is not up to specifications, bend the other spring bracket to give the correct advance.

Vacuum advance can be adjusted by changing the calibrated washers between the vacuum chamber spring and nut, Fig. 43. The addition of one washer will decrease advance and the removal of a washer will increase advance.

Distributor Service

If the distributor has been disassembled, refer to Fig. 42 for guidance upon reassembly.

1. Oil shaft and slide it into distributor body.
2. Place collar in position on shaft and align holes in collar and shaft, then install a new pin.
3. Install distributor cap clamps.
4. Check shaft end play with feeler gauge placed between collar and base of distributor. If shaft end play is not within .024-.035", replace shaft and gear.
5. Fill grooves in weight pivot pin with ball bearing grease.
6. Position weights in distributor.
7. Install weight springs, being sure proper weight, spring and adjustment bracket are assembled together.
8. Install upper thrust washer.
9. Fill grooves in upper portion of distributor shaft with ball bearing grease.
10. Install cam assembly, being sure that slots in cam engage pins in weights.
11. Install cam retainer. Apply a light film of cam lubricant to cam lobes. Saturate wick with 10W engine oil. Install wick in cam.
12. Position stationary sub plate in distributor. Install one end of ground wire under plate retaining screw close to diaphragm mounting flange.
13. Position movable breaker plate in distributor. Install spring washer on pivot pin. Place flat washer on spring washer. Be sure protruding edges of spring washer are facing upward. Install retainer.
14. Install new breaker point assembly. Install ground wire on breaker point attaching screw furthest from point adjustment slot.
15. Install condenser.
16. Working from inside to outside of distributor housing, pass primary wire through opening in distributor. Pull wire through opening until locating stop is flush with inside of distributor.
17. Connect condenser wire and primary wire to breaker points.
18. Position diaphragm and hook its link over pin on breaker plate. Install diaphragm attaching screws. Secure link with retainer. Install oil seal.
19. Adjust breaker arm spring tension, align and adjust breaker points and check and adjust cam dwell, centrifugal and vacuum advance.

Holley "Roto-Vance" Distributor

This distributor, Fig. 45, functions as a standard ignition unit and in addition acts as a control unit for the engine speed governor valves located below the carburetor, Fig. 46.

The distributor-governor consists of an adjusting nut, a calibrating spring and governor weight. Below governing speed the weight cannot overcome the spring tension and the air inlet port is open. Thus air is permitted to flow through the distributor shaft, the governor air line and through the engine governor. This air is at atmospheric pressure.

With an increase of engine speed and distributor shaft rotational speed, centrifugal force is exerted on the weight and it moves out against spring tension. Continued increases of engine speed moves the weight far enough to close off the air inlet port. Closing the air inlet port permits vacuum pressure to be impressed on one side of the engine governor diaphragm. The opposite side of the diaphragm is vented to atmospheric pressure through a connecting line to the fresh air inlet line. The resulting pressure differential on the diaphragm causes the throttle valve to be moved towards a partially closed position against the throttle valve plate governor spring tension.

A decrease in engine speed allows the distributor governor valve weight spring to push the weight towards the distributor shaft, thus opening the inlet port and neutralizing the pressure differential on the diaphragm. The governor throttle plate is returned to its fully open position by the engine governor spring.

Fig. 46 Diagramatic view of governor system. Holley "Roto-Vance" distributor

Fig. 47 Adjusting advance weight springs. Holley "Roto-Vance" distributor

Automatic Advance Adjustment

Install distributor on a test bench and remove the adjusting hole cover plug. Check the operation of the automatic advance against specifications given in Truck Chapters. Adjust the weight springs by screwing in or out on the adjusting nuts, Fig. 47, turning both nuts the same amount. Turning in on the nuts will increase the tension and the rpm required to move the weights and will give a retarded advance. Loosening the nuts will allow the weights to move at a slower rpm and will cause the timing to advance earlier. *Be sure nut flats index lock plate.* Where the initial setting is correct but the advance does not follow specifications it is an indication that the advance springs are faulty or the distributor cam is binding on the shaft.

CAUTION—Care should be taken when adjusting the advance mechanism to approximate the specified curve as closely as possible. The spark timing of the engine in operating range is determined directly by the accuracy of the distributor advance mechanism. *It is important to remember that a one-degree error in the distributor advance settings will produce a two-degree error in spark timing when operating in the engine.*

Testing Engine Speed Governor Valve In Test Stand

Operate the test stand vacuum pump. Pinch the end of the vacuum hose and record the highest vacuum reading obtained. Connect the vacuum line to the lowest fitting on the distributor. Make certain that no leaks are present.

Without rotating the distributor shaft, note the vacuum reading on the gauge. If the passages in the distributor are free of obstructions, a desirable very low reading should be obtained. An undesirable high reading will indicate that obstructions in the passages are present, caused by dirt or other causes. The distributor should then be thoroughly checked to determine cause and corrections made.

NOTE—Some test machines have a pipe cleaner type of restrictor. For these tests this restrictor should be removed or an inaccurate reading will be obtained. The vacuum line in the machine must be open.

Rotate the distributor shaft and gradually increase the speed while observing the vacuum gauge. When the distributor shaft speed reaches the rpm necessary to move the governor weight out on its shaft and close the air inlet port, the vacuum reading will "jump" to a high reading almost instantly. The vacuum reading at this rpm and at all higher speeds should be within one or two inches (Hg) of the reading recorded at the start of the test. If the vacuum reading is within the specified one to two inches of the previous reading, it is an indication that the weight valve is sealing the inlet port and that no noticeable leaks are apparent.

Decrease the distributor shaft speed gradually while observing the vacuum gauge. When the speed drops slightly below the governor closing speed, the air inlet port should open, causing a rapid drop in vacuum.

Delco-Remy Transistorized Ignition

Fig. DR1 Magnetic pulse distributor

Fig. DR2 Magnetic pulse distributor with cap removed

Fig. DR3 Ignition pulse amplifier

DESCRIPTION

Called the *Delcotronic Transistor Controlled Magnetic Pulse Ignition System*, it features a specially designed magnetic pulse distributor, an ignition pulse amplifier, and a special coil. The other units in the system are of standard design, consisting of the resistors or resistance wire, switch and battery. A typical distributor of this type is shown in Fig. DR-1.

Although the external appearance of the distributor resembles a standard distributor, the internal construction is quite different. As shown in Fig. DR-2, an inner timer core replaces the conventional breaker cam. The timer core has the same number of equally-spaced projections or vanes as engine cylinders.

The timer core rotates inside a magnetic pick-up assembly, which replaces the conventional breaker plate, contact point set, and condenser assembly. The magnetic pick-up assembly consists of a ceramic permanent magnet, a pole piece and a pick-up coil. The pole piece is a steel plate having equally-spaced internal teeth, one tooth for each cylinder of the engine.

The magnetic pick-up assembly is mounted over the main bearing of the distributor housing, and is made to rotate by the vacuum control unit, thus providing vacuum advance. The timer core is made to rotate about the shaft by conventional advance weights, thus providing centrifugal advance.

The ignition pulse amplifier shown in Fig. DR-3 consists primarily of transistors, resistors, diodes and capacitors mounted on a printed circuit panel board. Since there are no moving parts, the control unit is a completely static assembly.

Operating Principals

A wiring diagram showing the complete circuit for a typical ignition system is illustrated in Fig. DR-4. Note that

Fig. DR4 Wiring diagram of magnetic pulse distributor circuit

there are two separate resistors used in this type of circuit. The resistor connected directly to the switch is by-passed during cranking, whereas the other resistor is always in the circuit. The use of two resistors permits the required value of resistance to be by-passed during cranking.

In order to fire the spark plug, it is necessary to induce a high voltage in the ignition coil secondary winding by opening the circuit to the coil primary winding. In standard systems, this is accomplished by opening the distributor contact points. In this system, this is accomplished as follows:

When the switch is closed with the engine not running, the current flows through a part of the circuit, Fig. DR-5. The current flows from the battery through the switch and resistor R-6 to the amplifier. Current then flows through transistors TR-1 and TR-2, resistors R-1, R-2 and R-3, and the coil primary winding and resistor R-7 to ground, thus completing the circuit back to the battery. It is important to note that under this condition, full current flows through the coil primary winding, and capacitor C-1 is charged with the positive voltage towards transistor TR-2.

When the engine is running, the vanes on the rotating iron core in the distributor line up with the internal teeth on the pole piece. This establishes a magnetic path through the center of the pick-up coil, causing a voltage to be induced in the pick-up coil. This voltage causes transistor TR-3 to conduct, resulting in current flow in the circuit as shown in Fig. DR-6.

The current flow conditions shown in Fig. DR-6 exist until the charge on capacitor C-1 has been dissipated through resistor R-3. When this happens the system reverts back to the current flow conditions shown in Fig. DR-5. The system is then ready to fire the next spark plug.

Resistor R-5 is called a feedback resistor, and its purpose is to turn TR-3 off when TR-2 returns to the on condition. Resistor R-1 is a biasing resistor which allows transistor TR-1 to operate. Zener diode D-1 protects transistor TR-1 from high voltages which may be induced in the coil primary winding. Capacitors C-2 and C-3 protect transistor TR-3 from high voltages which appear in the system.

TROUBLE SHOOTING

Faulty engine performance will usually be evidenced by engine miss, engine surge, or the engine will not run at all. When trouble shooting the system, it is recommended that the following checks be made in the order listed.

Engine Miss

If the trouble is not due to carburetion, check the timing and the condition of the spark plugs. All the wiirng should be inspected for brittle or cracked insulation, broken strands and loose or corroded connections. The high tension leads in the coil and distributor cap should be checked to make sure they are pressed all the way down in their inserts. If rubber boots are used, they too should be tightly in place over the connections. Also, the outside of the distributor cap and the coil cover should be inspected for carbonized paths which would allow high tension leakage to

Fig. DR5 Wiring diagram showing current flow in solid lines with switch on and engine not running

Fig. DR6 Wiring diagram showing current flow in solid lines when spark plug fires

ground. Also, remove the distributor cap so the rotor and inside of the cap can be checked for cracks and carbonized paths.

Distributor—The pick-up coil in the distributor may be checked by separating the harness connector and connecting an ohmmeter across the coil. The resistance of the coil should be 300 to 400 ohms. If the reading is infinite (high off scale) the coil is open circuited; if the reading is low the coil is shorted. Remember that the resistance of the coil will increase slightly as the coil temperature rises.

Also, the pick-up coil may be checked for grounds by connecting the ohmmeter from either coil lead to the distributor housing. The reading should be infinite. If it is not the coil is grounded.

The distributor centrifugal and vacuum advance may be tested on a distributor testing machine. However, since this involves removing the distributor, delay this operation until after the remaining circuit checks are covered. Besides, it is not likely that the advance mechanism is the cause of the trouble.

Ignition Coil—The ignition coil primary can be checked for an open condition by connecting an ohmmeter across the two primary terminals. An infinite reading indicates the primary is open. For the engine to run but miss at times, the primary open must be of the intermittent type.

Also, the coil secondary can be checked for an open by connecting an ohmmeter from the high tension center tower to either primary terminal. To obtain a reliable reading, a scale on the ohmmeter having the 20,000 ohm value within, or nearly within, the middle third of the scale must be used. If the reading is infinite, the coil secondary winding is open. *If a coil tester is available, make sure the tester is designed to test this SPECIAL coil.*

Ignition Pulse Amplifier—If all previous checks are satisfactory, and the amplifier is properly grounded, the engine miss is probably caused by a defective ignition pulse amplifier. Replacement of the amplifier will determine if the original amplifier is defective.

Engine Surge

An engine surge condition, of a nature much more severe than that characterized by a lean carburetor mixture, may be due to the two distributor leads being reversed in the connector body, or may be due to an intermittent open in the distributor pick-up coil.

Fig. DR7 Voltmeter connections for circuit checks

The surge condition may result from the action of the vacuum unit causing a break in the distributor pick-up coil wiring to open and close intermittently. To check this, disconnect the vacuum line and observe engine behavior at idle speed.

To complete the checks on the pick-up coil, connect an ohmmeter to the two distributor pick-up coil lead terminals in the connector body. The resistance should be 300 to 400 ohms. If the resistance is infinite the coil is open, and if the resistance is low the coil is shorted.

Also connect the ohmmeter from either terminal to the distributor housing. The reading should be infinite. If not, the winding is grounded.

Engine Will Not Run

If the engine will not run at all, remove the lead from one of the spark plugs and hold it about ¼″ away from the engine block while cranking the engine. If a spark occurs, the trouble most likely is not ignition. If a spark does not occur, check the distributor, wiring and ignition coil as previously described. If these check out correctly, further check the circuit continuity as follows:

1. Connect a voltmeter as shown in Step 1, Fig. DR-7. Observe reading with switch on.
   a. If reading is 8 to 9 volts, check the distributor as outlined above.
   b. If reading is battery voltage, there is an open in the circuit between this point and ground. This circuit consists of coil primary winding, resistor and wiring.

c. If reading is zero, there is an open in the circuit between this point and the battery. Proceed with Step 2 as follows:

2. Connect voltmeter as shown in Step 2, Fig. DR-7. Observe reading with switch on.
   a. If reading is zero there is an open between this point and the battery. This circuit consists of the resistor, ignition switch and battery.
   b. If the reading is battery voltage, there is an open in the circuit between this resistor and ignition coil. This circuit consists of ignition pulse amplifier and the wiring. If the wiring checks satisfactorily, replace the amplifier.

MAINTENANCE

Since the ignition pulse amplifier is completely static, and the distributor shaft and bushings have permanent-type lubrication, no periodic maintenance is required. The distributor lower bushing is lubricated by engine oil through a splash hole in the distributor housing, and a housing cavity next to the upper bushing contains a supply of lubricant which will last between engine overhaul periods. At time of engine overhaul, the upper bushing may be lubricated by removing the plastic seal and then adding SAE 20 oil to the packing in the cavity. A new plastic seal will be required since the old one will be damaged during removal.

Ford Transistorized Ignition System

A transistor is a small electronic device that controls current through the peculiar conductive properties of an element called *germanium*. The transistor gets its name from the words "transfer resistance".

The transistor in an ignition system provides a means of furnishing greater current to the ignition coil with an accompanying greater secondary voltage for firing the spark plugs. At the same time it furnishes less current to the ignition contacts, thereby materially lengthening their life. This is accomplished by means of two inter-related primary ignition circuits whereas the conventional ignition system uses only one such circuit.

The system consists of a base circuit (low voltage trigger circuit), coil primary (collector) circuit (low voltage primary circuit), and a secondary (high voltage coil) circuit. The current will not flow in the primary circuit unless a current is flowing in the base circuit. A very small current in the base circuit allows a much larger current flow in the primary (collector) circuit.

Circuit Components F1, F2, F3

Base Circuit:
1. Battery.
2. Ignition switch.
3. Ballast resistor (.33 ohm).
4. Tach block.
5. Heat sink (toroid, transistor, condenser (40 mfd), and resistor (6 ohm).
6. Resistor.
7. Distributor.

Coil (Primary) Collector Circuit:
1. Battery.
2. Ignition switch.
3. Condenser (2 mfd).
4. Ballast resistor.
5. Tach block.
6. Heat sink (toroid and transistor).
7. Ballast resistor.
8. Coil primary.

Secondary Circuit:
1. Coil secondary.
2. Distributor cap and rotor.
3. Spark plugs.

Glossary

Transistor: A non-vacuum semi-conducting combination of chemical elements used in electrical circuits in place of vacuum tubes.

Zener Diode: A voltage regulating device and two element semi-conductor devices used to control the direction of electrical current flow.

Ballast: A current limiting element. A ballast resistor is a resistor to limit the current and keep it under control.

Tach Block: A block with exposed terminals for test equipment in or to an electrical circuit.

Heat Sink: A device for absorbing heat from electrical units and releasing the heat to the atmosphere to prevent overheating of the electrical units.

Toroid: A small doughnut shaped iron core around which coils of wire are wound similar to a transformer.

Operation

In actual operation, a ½ ampere current flows from the battery through the ignition contacts, the common .33 ohm emitter resistor, the ignition switch and returns to the battery.

This small control current permits the large 12 ampere current to flow from the battery, through the ignition coil, the .43 ohm collector resistor, the toroid, the transistor collector and emitter, the common .33 ohm emitter resistor, the ignition switch and back to the battery. Since this circuit supplies the power to the ignition coil, it is convenient to refer to it as the power circuit, or coil circuit.

During the dwell, when the ignition points are closed, current flows in both circuits. When the points begin to open, the collapsing magnetic field produced in the toroid sends a reverse pulse through the control circuit, stopping all electron flow in the control circuit. Because the control circuit triggers the power circuit, current stops in the power circuit also.

This causes the magnetic field, produced by the coil primary windings, to collapse, sending very high voltage into the secondary circuit to fire the spark plugs. In addition, high voltage is also induced in the primary windings of the power circuit.

This would be sufficient to cause transistor destruction, inasmuch as the induced voltage instantly rises above the load line of the transistor until it reaches the breakdown level of the zener diode. For this reason the condenser is incor-

Fig. F1 Ford transistorized ignition system

porated into the power circuit to absorb the high voltage current and keep it within load limits until the zener protection level is reached. Discharge of the condenser voltage from zener level to system voltage takes place by reverse flow through the power circuit, except that the transistor is by-passed by the diode which freely passes this reverse current.

Closing of the ignition points completes the cycle by closing the point circuit again and causing current flow in the power circuit.

Service Recommendations & Specifications

Because of the wide range and usage encountered by the types of vehicles using this ignition system, no set rules for service procedures can be established. However, general recommended procedure for diagnosing suspected ignition trouble in all but the 6-cylinder and dual point vehicles due to power loss is as follows:

1. If dwell is greater than 30 degrees, reset to 24 (plus or minus 1½) degrees.
2. If timing is as much as 4 degrees from specifications, reset to specifications.
3. Points normally need not be adjusted under 20,000 miles. Gap is .019-.021″.
4. Spark plugs may be cleaned and regapped at 50,000 miles although experience indicates that a much greater mileage should be expected. Gap is .028-.032″.
5. Use Chevron O.H.T. cam lubricant only.

Trouble Diagnosis

CAUTION: Discontinue previous underhood short cuts such as the use of jumper wires and grounding devices except those described in the following instructions. The use of these "conventional" diagnostic methods can cause extensive and unnecessary component damage to the transistor system.

1. Determine whether or not there is a spark by disconnecting coil-to-distributor high tension wire from the center terminal of the distributor cap. Turn on ignition and hold the loose end of the wire about ¼″ away from a good ground (clean engine block) while cranking engine. *Note: Engine may be cranked by jumping the ignition switch with a jumper wire from battery terminal to "S" terminal of starting relay after disconnecting the red and blue lead (nearest battery terminal).*
2. A good, strong spark, as measured by conventional standards, indicates satisfactory ignition operation. Reconnect coil high tension lead and test similarly for spark at spark plugs. A good spark at the plugs indicates the trouble to be other than ignition.
3. If the spark is weak or non-existent, remove cover from mounting plate and connect a dwell meter to the tach block (red to red and black to black). With ignition on, crank engine and observe meter reading. A dwell angle of less than 45 degrees indicates that the transistor is functioning properly and that the trouble is not in this component.
4. A dwell meter reading of zero indicates that the breaker points are contaminated or not closing and should be replaced or adjusted.
5. A dwell meter reading of 45 degrees indicates that: a) the ignition is not being supplied with power from ignition switch; b) breaker points are not opening; c) the transistor is malfunctioning. Disconnect bullet connector from distributor lead and again crank engine. A meter reading of zero indicates that the trouble is in the breaker points. A meter reading of 45 degrees indicates power source of transistor trouble. To determine which, connect a voltmeter or test lamp to the red/green lead terminal of the ballast resistor and crank engine. A meter reading of 45 degrees or steady light indicates transistor malfunction. Replace the amplifier assembly (transistor). Absence of any indication on meter indicates an open circuit between battery and transistor.
6. A weak spark in Steps 1 or 2 indicates a weak coil. Turn ignition off, replace with a new coil and repeat Step 1. *Do not attempt to test coil because its low impedence contributes to inaccurate indications.*
7. To jump ignition switch from under hood, disconnect red with green chaser lead from ballast resistor and connect a jumper from positive battery terminal to vacated ballast resistor blade terminal. The transistor ignition system will now be supplied with battery power, providing that the resistor is not open. Check this provision out before proceeding.
8. The only points from which to secure diagnostic information are the tach block terminals ballast resistor terminals and the distributor primary bullet connector. *Do not pierce insulation elsewhere* with sharp probes or pointed objects for a more comprehensive analysis unless all other tests have failed to

Fig. F2 Ford transistorized ignition circuit

Fig. F3 Ford transistorized ignition wiring diagram

reveal a known ignition malfunction cause. By connecting a voltmeter and ammeter at these points, with a well charged battery and the brown lead disconnected from the cold start relay, cranking amperages and voltages may be obtained which should correspond to the data shown in Fig. F-4.

GENERATOR SERVICE

Removing Generator

Figs. 1 and 2 illustrate a typical generator. The following contains tips on servicing and replacing the generator. To replace the brushes, it is assumed that the generator is to be removed from the engine.

1. Remove the leads from the generator terminals, Fig. 3. Identify each lead in order that it can be replaced to the proper terminal. Note that the condenser (for radio suppression) is always attached to the "A" terminal and never to the "F" terminal.
2. The fan belt must be removed from the generator pulley. On some cars it is necessary to remove the nut holding the belt tension idler pulley in place. With tension loosened, the belt can be removed.
3. Remove the generator by removing the bolts holding the generator lugs to the engine mounting bracket, Fig. 4. On some cars, it is necessary to remove the stud holding the adjusting bracket to generator end frame, Fig. 5. Then loosen the nuts holding the generator to the engine mounting bracket. Move generator toward the engine to release the belt from the pulley. Remove mounting bolts and lift generator from bracket.
4. Some applications have a power steering pump driven by an extended generator shaft, Fig. 6. To remove this type generator, the pump must first be removed from the generator by loosening the two mounting screws. The pump can then be pulled off and the generator removed from the engine as previously described.

Fig. 2 Exploded view of generator

Fig. 3 Note that condenser is attached to the "A" terminal. If connected to the "F" terminal it would make the voltage regulator ineffective and the generator would overcharge

Fig. 4 Typical generator mounting

Fig. 5 Removing stud holding adjusting bracket to generator end frame

Replacing Brushes

1. Remove commutator end frame by first removing the through bolts. Some types of through bolts have hex heads whereas others have slotted screw heads. After bolts are removed, it may be necessary to lightly tap the end frame to remove it from the field frame, Fig. 7.
2. Remove drive end frame and armature assembly from field frame, Fig. 8.
3. With a cloth, clean inside of field frame assembly. *Do not dip field coils in any cleaning solvent or puncture field coil insulation during the cleaning process.*

GENERATOR NOT CHARGING

1. To check out the trouble, first make sure all connections at the generator and the regulator are clean and tight. Then run the engine at a fast idle speed. If the generator still fails to show a charge, proceed with Step 2. But if a charge is indicated on the ammeter or if the indicator light goes out, there was a poor connection in the circuit.
2. If the generator field is internally grounded, connect a jumper wire from the regulator armature terminal to the field terminal. If the generator field is grounded externally through the regulator, ground the field terminal to the regulator base. In both cases, the regulator has been taken out of the circuit. Again run the engine, and if the generator now shows a charge the regulator is at fault.

Caution

The foregoing procedure should not be used with double contact voltage regulators. With external ground systems (Delco-Remy), disconnect the field lead and ground it to the regulator base. With internal ground systems, disconnect the field lead and hold it against the armature terminal of the regulator. If this is not done, the lower set of contacts will burn, thereby making the regulator inoperative.

3. If there is still no charge after the foregoing test, short out the circuit breaker and current regulator by connecting a jumper wire from the regulator armature terminal to the battery terminal. Again run the engine, and if the generator now shows a charge, the regulator is at fault. However, if there is still no charge, the trouble is probably in the generator itself, although it may be elsewhere in the charging circuit.
4. Clean commutator end frame, using a cloth dampened in solvent. Place a drop or two of oil in the bushing type bearing to facilitate reassembly.
5. Clean the armature and drive end assembly with an air hose. A clean dry rag may be used to wipe off dirt if an air hose is not available. *Do not use solvent of any kind on the armature.*
6. Examine commutator for high bars, high mica, pitted bars, or excessive wear. If any of these conditions are found, the commutator should be turned down on a lathe and the mica undercut, Figs. 9, 10, 11. Burned bars may indicate a defective ar-

Fig. 6 Removing power steering pump from generator

Fig. 9 Turning down commutator with a lathe

Fig. 10 Undercutting mica insulation. Depth of cut should be 1/32"

Fig. 11 Examples of proper and improper undercutting

Fig. 12 Testing armature for short circuit. As armature is rotated by hand, steel strip (hacksaw blade) will vibrate if short circuit exists

mature which should be tested and replaced if necessary, Figs. 12, 13, 14.

7. If commutator appears to be in good condition except for dirt or minor corrosion, it may be cleaned with a fine grade of sandpaper. After cleaning, blow out abrasive particles left between commutator bars. *Never use emery cloth for this purpose as particles of emery may become embedded in the commutator bars and cause a short.*
8. Remove brushes from field frame. Wipe off brush holders with a rag dampened in solvent. Any corrosion on the brush bearing surface of the brush holders should be removed to permit freedom of brush movement.
9. If brush holders are mounted on the commutator end frame, remove necessary screws allowing complete removal of brushes.
10. Generators with cover bands need not be disassembled, unless so desired, for brush replacement. First remove the cover band and then remove the screws that attach the flexible brush leads to the brush holders. Then lift up on the brush spring arm and pull out the old brush. A new brush is then pushed down into position in the brush holder. The flexible leads of the brush are then re-fastened to the brush holder. If a field coil lead is present, it also must be fastened to the proper brush holder at this same time.
11. To insert new brushes into the brush holders attached to the field frame, push brush into holder from the bottom and shove it up all the way. This will allow the brush arm to lock the brush up into a position for installation over the commutator. Refasten flexible leads to commutator.
12. When brushes are installed, make sure the pre-formed angle on the brush matches the commutator contour.
13. Generators with brush holders mounted to the commutator end frame of the type shown in Fig. 15, should have their brushes inserted and flexible leads securely fastened in place before reassembling the end frame onto the field frame.
14. On some generators the brushes may be seated as shown in Fig. 16, using No. 00 sandpaper cut as wide as the commutator finished surface. Excessive use of sandpaper should be avoided since it will shorten the brush and decrease its life. Blow off abrasive dust and carbon after completing the seating process.
15. Another method of seating brushes after the generator is reassembled is to spread some brush seating compound on the commutator and then turn the armature by hand for 20 or 30 revolutions. Then blow out the carbon and dust residue left from the brush seating operation.
16. Before reassembling the generator, it may be desirable to check out the field coils and terminals. If so refer to Figs. 17 to 20
17. When reassembling generators, make sure brushes are out of the way when brush assembly is slipped over commutator. In the event brushes are held up by the brush arm, make sure they are seated down on commutator before installing generator on engine.

Replacing With New Generator

1. When exchanging the existing generator with a new or replacement generator, it is necessary to remove

Fig. 13 Armature test for ground. Using test lamp, place test lead on armature core and the other lead on each commutator bar. If lamp lights armature is grounded and must be replaced

Fig. 14 Armature test for open circuit

Fig. 15 Brushes mounted to commutator end frame

Fig. 16 Seating brushes with sandpaper

Fig. 17 Field coil test for open circuit. Using test lamp, place one test lead on field terminal and the other on the field coil lead to armature terminal. If lamp does not light, field coils are open and must be replaced (unless a loose soldered connection is found at field terminal)

Fig. 18 Field coil test for ground. Using a test lamp, place one test lead on generator frame (ground) and the other on field terminal. Be sure free end of field wire is not touching ground and field terminal insulation is not broken. If lamp lights, field coils are grounded. If ground cannot be located or repaired, field coils must be replaced

the pulley and fan assembly from the old generator for use on the new generator. After the generator has been removed from the engine, it may be possible to remove the pulley nut by holding the pulley armature shaft by a belt, Fig. 21.

2. In the event that the pulley nut cannot be loosened by the belt method, it is necessary to disassemble old generator to remove the pulley, armature and drive end frame assembly. This assembly can then be placed in a vise and the pulley nut removed.
3. A pulley puller is then used to remove the pulley from the armature shaft, Fig. 22. Care should be exercised not to bend or distort either the pulley or fan blades during the removal process.
4. The fan and pulley assembly is then placed over the new generator shaft with the keyway in position over the key. Then lightly tap the pulley and fan assembly down on the shaft until the pulley nut can be started on the threaded end of the shaft.
5. After the generator is assembled and brushes properly seated the generator should be run as a motor, the procedure for which is given below. Mount the generator on the engine and tighten the pulley nut to force the pulley into position against the armature shaft shoulder. Use the vehicle belt as a holding device on the pulley.
6. Apply 8 to 10 drops of light engine oil to the oil cups if present on the generator. Sealed bearings do not require lubrication.

POLARIZING GENERATOR

After the generator is installed on the engine and all leads are connected, the generator must be polarized before starting the engine. The polarizing procedure depends upon whether the field is grounded externally or internally. This data is included in the *Generator and Regulator Specifications* charts in the vehicle chapters. Having determined which system is used, proceed as follows:

If the generator field is externally grounded, Fig. 23, momentarily connect a jumper wire from the "BAT" to the "GEN" or "ARM" terminals of the voltage regulator. Just a touch of the jumper to both terminals is all that is required:

If the generator field is internally grounded, Fig. 24, disconnect the field wire from the regulator and momentarily touch this wire to the regulator "BAT" terminal.

MOTORING GENERATOR

Run the generator as a motor by connecting the ground side of a battery to the generator housing. Connnect the ungrounded side of the battery to the generator armature terminal.

On generators with externally grounded fields, connect a jumper wire from the generator field terminal to the generator frame. For internally grounded units connect a jumper wire from the armature terminal to the field terminal.

Fig. 19 Armature terminal test for ground. Using a test lamp, place one test lead on armature terminal and the other on generator frame. Be sure loose end of terminal lead is not touching ground. If lamp lights, armature terminal insulation through generator frame is broken down and must be replaced

Fig. 20 Insulated brush holder test for ground. Using a test lamp, place one test lead on insulated brush holder and the other on ground. If lamp lights, brush holder is grounded due to defective insulation on frame

Fig. 21 Holding pulley tight with fan belt while loosening or tightening pulley nut

Fig. 22 Using puller to remove pulley

Fig. 23 Wiring diagram of a generator having the field grounded externally through the voltage regulator. This can readily be identified by the fact that the grounded brush has only its own lead connected to it

While motoring, the armature should rotate slowly. If it does not, it may be due to improper bearing fit or alignment, mechanical interference between armature and field coil pole shoes or improper end play. If end play appears excessive, check the tightness of the pulley nut. Make sure that the pole shoe screws are securely tightened. Two or three sharp raps on the generator frame with a rawhide or plastic hammer will often help to free the armature.

VOLTAGE REGULATORS, REPLACE

1. When working on voltage regulators, it is good practice first to remove the battery ground strap or cable from the battery post. This prevents any short circuits or accidental grounds from occurring.
2. To aid in correctly re-wiring to the replacement regulator, identify the wires in some manner that will aid in proper installation.
3. Remove lead or leads connected to the battery terminal of the regulator.
4. Remove lead or leads connected to the armature terminal of the regulator. This terminal is marked "GEN" on Delco-Remy units, and "A" or "ARM" on Autolite, Ford and Bosch units. *If a condenser is present, note that it must be connected to the armature terminal only.*
5. Some regulators have a fuse connected to the regulator battery terminal. This fuse should be removed for use with the replacement regulator. Before installing the fuse, however, it should be tested for continuity with a test lamp. This is to make sure the fuse is not defective or "blown" which would result in an open circuit.
6. After the new regulator has been installed in position, scrape all lead connections or terminals clean to provide a good metal-to-metal contact when re-connected to the regulator terminals.
7. After all leads are connected and before the engine is started, the generator must be polarized as outlined previously.

ELECTRICAL TESTS ON REGULATORS

Service Notes

1. Do not attempt to adjust regulators unless its operation is thoroughly understood and accurate meters are available. Even a slight error in the setting of the unit may cause improper functioning, resulting in a run-down or overcharged battery, or damage to the generator or regulator.
2. When electrical tests are made at the regulator terminals, there is great danger of short circuiting the regulator and burning the contact reeds on Autolite units. Whenever possible it is better to connect test apparatus where there is no danger

Fig. 24 Wiring diagram of a generator having the field grounded internally through the grounded brush. This can readily be identified by the fact that the grounded brush has both its own lead and the field lead connected to it

Fig. 25 Auto-Lite, Ford and Bosch regulator contacts should be filed parallel with length of armature

Fig. 26 Cleaning Delco-Remy regulator contact points

Fig. 27 Circuit breaker test for Auto-Lite, Ford and Bosch regulators

Fig. 28 Adjusting circuit breaker closing voltage on Ford and Bosch regulators

Fig. 29A Adjusting armature spring tension for Auto-Lite voltage and current settings

Fig. 29 Voltage regulator test on Auto-Lite, Ford and Bosch single contact voltage regulators

Fig. 30 Adjusting voltage regulator (left) and current regulator (right) on Ford and Bosch regulators

of damaging the regulator. For example:

3. When checking generator output on single contact voltage regulators, ground the field terminal at the generator rather than at the regulator to avoid the possibility of grounding the regulator battery terminal with a screwdriver. *Caution: When making this test on double contact voltage regulators, disconnect the field lead from the generator and ground this lead to the generator frame.*
4. Timing or trouble lights should be connected at the starter solenoid terminal rather than at the regulator battery terminal. This will avoid danger of the clip connector slipping off and simultaneously touching the battery and field terminal of the regulator.
5. Before testing or adjusting the regulator, be sure all connections in the charging circuit are clean and tight, and that the battery is fully charged. Check the generator output and be sure the regulator is the correct unit for use with the particular generator. Be sure regulator is properly grounded.
6. Always make the voltage regulator test before making the current regulator test. When removing or installing the regulator cover, do not allow the cover to touch regulator parts, as this might cause a short circuit and damage the unit.
7. Before starting the tests make sure the contacts are clean and not rough or pitted. If this is not done, subsequent tests will only produce erratic meter indications. When cleaning Autolite, Ford and Bosch contacts, they should be filed parallel to the armature as shown in Fig. 25, using a No. 6 American Swiss cut equaling file. Do not file crosswise as grooves may form which would tend to cause sticking and erratic operation. Delco-Remy recommends the use of a spoon or riffler file, Fig. 26. After filing, use a strip of linen tape dampened with lighter fluid to clean the contacts; then run a strip of dry tape across the points to remove any residue left from filing.

AUTOLITE, FORD & BOSCH ELECTRICAL TESTS

Circuit Breaker

1. With an ammeter connected as shown in Fig. 27, and a voltmeter connected from regulator armature terminal to regulator base, disconnect field lead from regulator field terminal and insert a variable resistance between field lead and its terminal.
2. Run engine at about 800 rpm. Turn variable resistance to the "all in" position. Then slowly reduce the resistance, noting the voltage reading just as the circuit breaker closes. The voltmeter will give a sharp fluctuation at that point and usually a slight click can be heard as the contacts close.
3. On Autolite units, if the closing voltage is not within specifications,

Fig. 31 Adjusting Ford and Bosch double contact voltage regulator

Fig. 32 Current regulator test on Auto-Lite, Ford and Bosch regulators

Fig. 35 Checking Delco-Remy voltage regulator setting

remove the regulator cover and change the armature spring tension by bending the lower spring hanger. Bending the spring hanger down increases spring tension and raises the voltage, and vice versa.

4. If closing voltage is not within specifications on Ford and Bosch units, bend the adjusting arm upward to increase voltage, and vice versa, Fig. 28.

Single Contact Voltage Regulator

1. Leave the ammeter connected as shown and move the voltmeter clip from the regulator armature terminal to the regulator battery terminal, Fig. 29.
2. Disconnect the variable resistance from the regulator field terminal and reconnect the field lead. Then insert a ¼ ohm fixed resistor in series with the ammeter.
3. Increase engine speed to obtain about a 7 ampere charge and operate for about 15 minutes with regulator cover in place.
4. Stop and restart the engine to cycle the generator; then note voltage reading. If not within specifications, adjust as follows:
5. On Autolite units, adjust by bending lower spring hanger, Fig. 29A. Bending the hanger down increases spring tension and raises voltage and vice versa.
6. On Ford and Bosch units, increase spring tension by bending adjusting arm upward to raise voltage and vice versa, Fig. 30.
7. Be sure to stop and restart engine and replace cover after each setting before taking voltage readings.

Ford & Bosch Double Contact Voltage Regulator

If proper voltage cannot be obtained by bending the spring hanger as directed for single contact voltage regulators, further adjustments are required as follows:

1. Disconnect ground terminal from battery.
2. Remove regulator from vehicle and take off cover.
3. Turn upper contact screw in or out to obtain a .040" gap between armature core and armature, Fig. 31.
4. Turn lower contact screw in or out to obtain a .037" gap between armature core and armature. While making adjustments, hold contact points together by pressing downward on screwdriver.

Current Regulator

1. Meters are connected as for the voltage regulator test except that the fixed resistor is removed and a carbon pile rheostat is connected across the battery as shown in Fig. 32 to allow full output. An alternate method for allowing the current regulator to operate is to operate the starting motor for 15 or 20 seconds cranking the engine and turning on lights and accessories.
2. Operate engine at about 1800 rpm. Using the carbon pile, increase the load to lower the regulated system voltage approximately one volt and allow the current regulator to operate.

Fig. 37 Delco-Remy regulator adjusting screws

Fig. 38 Proper contact between regulator spring support and adjusting screw on Delco-Remy regulators

3. When a steady reading is reached which cannot be increased by a slight increase in engine speed, this will be the current regulator setting.
4. After operating at full output for 15 minutes, the current regulator should be within specified limits at operating temperature.
5. Adjustment is made in the same manner as for the voltage regulator.

DELCO-REMY ELECTRICAL TESTS

Figs. 33 and 34 show the generator circuit using single contact voltage regulator and double contact voltage regulator, respectively. In making the following tests, the regulator must be at operating temperatures before taking meter readings. Operating temperature may be assumed to exist after not less than 15 minutes continuous operation with a charging rate of about 10 amperes and regulator cover in place.

CAUTION: With charging circuits having the double contact voltage regulator, Fig. 34, it is extremely important never to ground the field terminal of the generator or regulator when these units are connected or operating together. To do so will burn up the upper set of voltage regulator contacts.

For best results, the electrical tests must be made in the order given below.

Single Contact Voltage Regulator

1. Make meter connections as shown in Fig. 35 (upper view), and operate the engine at about 1600 rpm for 15 minutes with the ¼ ohm resistor in the circuit and cover in place to bring the regulator to operating temperature.
2. Cycle the generator by stopping the engine, then restarting and bringing generator speed back to 1600 engine rpm.
3. Note voltmeter reading and ambient temperature (temperature of air surrounding regulator ¼″ from cover). The voltage reading represents setting at ambient temperature. As shown in Fig. 36, setting will be different at other ambient temperatures. *If method of measuring ambient temperature is not available it may be assumed to be 40 degrees above room temperature.*
4. To adjust voltage setting, remove regulator cover and turn voltage regulator adjusting screw. Fig. 37. Turn screw clockwise to increase spring tension and raise voltage, and vice versa. *Final adjustment should always be made by turning screw clockwise to assure contact between screw head and spring support, Fig. 38.*
5. After each adjustment and before taking meter reading, replace cover and recycle generator, as in Step 2.

Double Contact Voltage Regulator

1. Make meter connections as shown in Fig. 35 (lower view).
2. With variable resistance turned out (minimum resistance), operate generator at a speed so that the voltage regulator is operating on the upper set of contacts. Continue to operate for 15 minutes to establish operating temperature. Regulator cover must be in place.
3. Cycle generator by turning variable resistance to the "open" position momentarily, then slowly decrease

REGULATOR AMBIENT TEMPERATURE	VOLTAGE LOW		VOLTAGE HIGH
205° F	13.3	—	14.1
185° F	13.4	—	14.2
165° F	13.5	—	14.4
145° F	13.7	—	14.5
125° F	13.8	—	14.6
105° F	14.0	—	14.8
85° F	14.1	—	14.9

NORMAL SPECIFICATION RANGE

Fig. 41 Delco-Remy circuit breaker test

Fig. 42 Delco-Remy current regulator test

Fig. 43 Checking for oxidized regulator contact points. On double contact regulators do not use jumper wire as shown; instead remove lead from "F" terminal and ground this lead

Fig. 44 Checking air gaps on Auto-Lite regulators

Fig. 45 Checking air gap on Auto-Lite circuit breaker

(turn out all) resistance. Regulator should again be operating on the upper set of contacts.

4. Note voltmeter reading and ambient temperature, and see Fig. 39 for correction factors.
5. Increase (turn in) resistance slowly until voltage regulator begins to operate on the lower set of contacts. The lower set should operate at a lower voltage than the upper set of contacts.
6. To adjust voltage setting on upper set of contacts, do so in the same manner as directed for single contact voltage regulators above.
7. For the lower set of contacts, the difference in voltage between the upper set and lower set is increased by *slightly* increasing the air gap between the armature and center of core and decreased by *slightly* decreasing the air gap, Fig. 40. This adjustment is made while the regulator is operating. If necessary to make this adjustment, recheck the voltage setting of both sets of contacts.

Circuit Breaker Closing Voltage

1. Make connections as shown in Fig. 41.
2. Check closing voltage by slowly increasing generator speed and noting voltage at which points close. Decrease generator speed and make sure points open.
3. If not as specified, adjust voltage by turning adjusting screw clockwise to increase voltage and vice versa (see Fig. 37).

Current Regulator

1. Before making connections shown in Fig. 42, disconnect battery ground lead. After completing the hook-up, reconnect battery lead.
2. Turn on all lights and accessories and connect an additional load across the battery, such as a carbon pile or bank of lights, so as to drop the system voltage to 12.5-13.0 volts.
3. Operate generator at 1600 engine rpm for at least 15 minutes with cover in place to establish operating temperature.
4. Cycle the generator as previously directed and note current regulator setting.
5. Adjustment is made in the same manner as outlined for single contact voltage regulators (see Fig. 37).

Check For Oxidized Contacts

1. Oxidized contacts may be the cause of low generator output or a discharged battery. To check for this condition, connect an ammeter into the circuit as shown in Fig. 43, and turn on headlights.
2. Operate generator at a speed that will produce a charge rate of 5 amperes.
3. Ground the "F" terminal of regulator as shown. *Caution: On double contact regulators, remove lead from "F" terminal and ground this lead.*
4. If generator output increases more than 2 amperes, oxidized contact points are indicated. Remove regulator from vehicle and clean points.

AUTOLITE MECHANICAL ADJUSTMENTS

Current & Voltage Regulator Air Gaps

1. Use a pin type gauge which measures .048-.052". Insert gauge on point side of air gap and next to armature stop pin with contact points just separating, Fig. 44.
2. If an adjustment is necessary, loosen bracket screws and raise or lower

Fig. 46 Adjusting air gap on Auto-Lite circuit breaker

Fig. 47 Adjusting air gap on Delco-Remy circuit breaker

Fig. 48 Adjusting point opening on Delco-Remy circuit breaker

contact point brackets until the foregoing clearance is obtained. Tighten screws securely after adjustment.

3. With armature held down so that stop rivet rests on magnet core, the point gap should be .015" when checked with a feeler gauge.

Circuit Breaker Air Gap

1. As shown in Fig. 45, use a flat gauge which measures from .031-.034". In-

Fig. 49 Adjusting air gap on late type Delco-Remy single contact voltage regulator

Fig. 50 Adjusting air gap on early type Delco-Remy single contact voltage regulator

Fig. 51 Adjusting point opening on early type Delco-Remy double contact voltage regulator

sert gauge between armature and magnet core. Place gauge as near to hinge as possible.

2. To adjust, bend armature stop, Fig. 46, so that space between core and armature is within the foregoing limits. The stop must not interfere with armature movement.
3. Adjust the contact gap to .015″ by expanding or contracting the stationary contact bridge, Fig. 46. When making this adjustment, keep the contact points in alignment.

DELCO-REMY MECHANICAL ADJUSTMENTS

Circuit Breaker Air Gap & Point Opening

1. Place fingers on armature directly above core and move armature down until points *just* close. Then measure air gap between armature and center core, Fig. 47. Air gap should be .020″.
2. Check to see that both points close simultaneously. If not, bend spring finger so that they do.
3. To adjust air gap, loosen two screws at back of circuit breaker and raise or lower armature as required. Tighten screws securely after adjustment.
4. Check point opening with feeler gauge as shown in Fig. 48 and adjust to .020″ by bending upper armature stop.
5. After both adjustments have been made, recheck closing voltage and make any necessary adjustments.

Voltage Regulator Air Gap On Single Contact Units

1. Referring to Fig. 49, push armature down to core and release it until contact points *just* touch. Then measure air gap with pin gauge between armature and center of core. Air gap should be .075″.
2. On late units, adjust gap by turning nylon nut on top of regulator as shown. On earlier units, adjust as shown in Fig. 50.
3. After making adjustment, recheck voltage setting and make necessary adjustments.

Voltage Regulator Air Gap & Point Opening On Double Contact Units

Point Opening

1. With lower contacts touching, measuse point opening between upper set of contacts. The opening should be .016″.
2. On early units, adjust as shown in Fig. 51. On late units, adjust as shown in Fig. 52.

Air Gap

1. On late units, Fig. 53, with lower contacts touching, measure air gap and adjust as shown.
2. On early units, first make sure adjusting screw on top of armature is turned all the way in a clockwise direction. Then check and adjust the gap as shown in Fig. 54.

Current Regulator Air Gap

Check and adjust current regulator air gap in exactly the same manner as the single contact voltage regulator. Air gap should be .075″. After making the adjustment, recheck current setting and adjust as required.

Fig. 52 Adjusting point opening on late type Delco-Remy double contact voltage regulator

Fig. 53 Adjusting air gap on late type Delco-Remy double contact voltage regulator

Fig. 54 Adjusting air gap on early type Delco-Remy double contact voltage regulator

FORD & BOSCH MECHANICAL ADJUSTMENTS

No mechanical adjustments are provided on these regulators as they are of riveted construction. However, on double contact regulators, the upper and lower voltage regulator contact sets are provided with an adjustment. See text in connection with Fig. 31.

INTRODUCTION

Alternators under discussion here are of the modern type with built-in silicon diode rectifiers. Under normal operating conditions, these alternators have a rating of 30 to 60 amperes, depending upon the requirements of the vehicle, and usually deliver 5 to 10 amperes at curb idle speed.

Alternators are composed of the same functional parts as the conventional D.C. generator but they operate differently. The field is called a rotor and is the turning portion of the unit. A generating part, called a stator, is the stationary member, comparable to the armature in a D.C. generator. The regulator, similar to those used in a D.C. system, regulates the output of the alternator-rectifier system.

The power source of the system is the alternator. Current is transmitted from the field terminal of the regulator through a slip ring to the field coil and back to ground through another slip ring. The strength of the field regulates the output of the alternating current. This alternating current is then transmitted from the alternator to the rectifier where it is converted to direct current.

These alternators employ a three-phase stator winding in which the phase windings are electrically 120 degrees apart. The rotor consists of a field coil encased between interleaved sections producing a magnetic field with alternate north and south poles. By rotating the rotor inside the stator, the alternating current is induced in the stator windings. This alternating current is rectified (changed to D.C.) by silicon diode rectifiers and brought out to the output terminal of the alternator.

Diode Rectifiers

Six silicon diode rectifiers are used and act as electrical one-way valves. Three of the diodes have ground polarity and are pressed or screwed into a heat sink which is grounded. The other three diodes (ungrounded) are pressed or screwed into and insulated from the end head; these diodes are connected to the alternator output terminal.

Since the diodes have a high resistance to the flow of current in one direction and a low resistance in the opposite direction, they may be connected in a manner that allows current to flow from the alternator to the battery in the low resistance direction. The high resistance in the opposite direction prevents the flow of current from the battery to the alternator. Because of this feature no circuit breaker is required between alternator and battery.

SERVICE PRECAUTIONS

1. Be certain that the battery polarity of the system is known so that the battery is connected to the proper ground. *Reversed battery polarity will damage rectifiers and regulator.*
2. If a booster battery is used for starting the vehicle, it must be connected to the vehicle battery properly to prevent damage to rectifiers and regulator. Negative cable from booster battery to negative terminal on vehicle battery, and positive booster cable to positive terminal.
3. When a fast charger is used to charge a vehicle battery used with Auto-Lite and Chrysler systems, the vehicle battery cables should be disconnected *unless the charger is equipped with a special Alternator Protector,* in which case the vehicle battery cables need not be disconnected. Also with Chrysler and Auto-Lite systems the fast charger should never be used to start an engine as damage to rectifiers will result.
4. Lead connections to grounded rectifiers on Auto-Lite and Chrysler units should never be soldered as the excessive heat may damage the rectifiers.
5. Unless the system includes a load relay or field relay, grounding the alternator output terminal will damage the alternator and/or circuits. This is true even when the system is not in operation since no circuit breaker is used and the battery is applied to the alternator output terminal at all times. The field or load relay acts as a circuit breaker in that it is controlled by the ignition switch.
6. When adjusting the voltage regulator, do not short the adjusting tool to the regulator base as the regulator may be damaged. The tool should be insulated by taping or by installing a plastic sleeve.
7. Before making any "on vehicle" tests of alternator or regulator, the battery should be checked and the circuit inspected for faulty wiring or insulation, loose or corroded connections and poor ground circuits.
8. Check alternator belt tension to be sure belt is tight enough to prevent slipping under load.
9. The ignition switch should be off and the battery ground cable disconnected before making any test connections to prevent damage to the system.
10. The vehicle battery must be fully charged or a fully charged battery may be installed for test purposes.

Chrysler Alternators

TESTING THE SYSTEM

Installed In Vehicle

With the battery fully charged and in good condition and engine at normal operating temperature, test the system as follows after first checking the fuse between the regulator and ignition switch. Also see Figs. C1 to C4.

Caution: Never ground the field circuit between the alternator and regulator as this will result in damage to the voltage regulator.

Charging Circuit Resistance Test

1. Remove output lead from alternator battery terminal and connect a D.C. ammeter between the terminal and the disconnected lead.
2. Connect a D.C. voltmeter positive lead to the output lead that was disconnected from the alternator and connect the voltmeter negative lead to the battery positive post.
3. Start the engine and adjust its speed to produce 10 amperes from the alternator. The voltage reading should not exceed .2 volt. If there is a higher voltage drop, clean and

tighten all connections in the charging circuit and recheck. A voltage drop test across each connection will locate any bad connections.

Current Output Test

1. Disconnect field lead at alternator and at regulator.
2. Install a D.C. ammeter in series with the alternator battery terminal and the wire disconnected from the alternator output terminal.
3. Connect a jumper between the battery terminal and the alternator field terminal.
4. Connect a carbon pile rheostat across the battery.
5. Connect a voltmeter positive lead to the alternator battery terminal and ground the voltmeter negative lead to the alternator housing.
6. Install a tachometer, start engine and adjust engine speed to 1250 rpm.
7. Adjust carbon pile to obtain 40 amperes while making tests. Turn off immediately when test is completed. The current output should be as specified in the *Alternator Specifications* table in the vehicle chapter. *If the output is low, the stator or a rectifier is shorted.*
8. Adjust engine speed to 2200 rpm. If output is excessive, a rectifier is open. If output is low a rectifier is shorted.

Voltage Regulator Test

1. Disconnect lead from alternator output terminal. Connect an ammeter between battery terminal and disconnected wire.
2. Connect a D.C. voltmeter positive lead to the alternator battery output terminal and ground the voltmeter negative lead to the alternator housing or regulator base.
3. Start the engine and adjust its speed to 1400 rpm and with ammeter reading 10 amperes by turning on lights, etc. Operate engine for 15 minutes to stabilize temperature (regulator cover in place). Check temperature with a thermometer two inches from regulator cover.

Fig. C1 Wiring hook-up for Chrysler alternator system

Fig. C4 Rotor assembly

Fig. C2 Chrysler alternator

Fig. C3 Stator and rectifier end housing assembly

Fig. C5 Checking regulator armature air gap

Adjust engine speed to 1250 rpm. With 15 amperes flowing in the circuit, the voltage should be as given in the specifications table in the vehicle chapter.

4. Then increase engine speed to 2200 rpm with five amperes flowing. Voltage should not exceed previous readings by more than .7 volt.
5. If voltage specifications are not met, remove regulator for adjustment.

Voltage Regulator Adjustments

In making adjustments, do not short circuit between spring hanger and base or spring. Grounding the spring hanger will damage the regulator.

Service Note

The voltage regulator cover is retained by the regulator mounting screws. Therefore, each time it is necessary to adjust the voltage regulator, the assembly must be removed from the vehicle. As it may be necessary to remove the regulator several times to obtain the proper adjustment, it is suggested that a push-on regulator cover be used as a tool in adjusting regulators.

When a push-on cover is used, it is necessary to remove the regulator assembly from the vehicle to remove the original cover. The push-on cover is then used while performing the adjustment and testing operations. After the final adjustment has been made, reinstall the original cover.

A push-on cover tool can be made from a discarded regulator by bending the cover legs in such a manner that it will stay in place when pushed on.

Armature Air Gap

1. Check air gap with a test lamp connected between ignition and field terminals on regulator.
2. Insert a .048″ wire gauge, Fig. C5.
3. Press armature plate down (not contact spring). Contacts should open and test lamp should go dim.
4. Insert a .052″ gauge in same position and depress armature plate. Upper contacts should be closed and test lamp should remain lighted.
5. Bend upper contact support as necessary to obtain proper adjustment.

Point Gap

Set lower contact gap to .015″ (plus or minus .001″) by bending lower contact arm. Press armature plate down so that armature rests on nylon stop. Release and recheck gap.

Spring Tension

Always make this adjustment by bending lower spring hanger, Fig. C6. If voltage was found to be too high, bend lower hanger *up*. If voltage was too low, bend lower hanger *down*.

Install regulator and repeat tests outlined previously. If further adjustment is necessary, adjust spring tension only. *If adjustment is attempted on the vehicle, do not short circuit between spring hanger and base as regulator will be damaged.*

BENCH TESTS

Field Circuit

1. Disconnect field teminal wire at alternator and at voltage regulator.
2. Connect a D.C. ammeter positive lead to the alternator battery output terminal.
3. Connect the ammeter negative lead to the alternator field terminal.
4. The field current draw should be as specified in the table in the vehicle chapter while turning the rotor shaft manually.

Testing Rectifiers

The procedure for testing rectifiers in the Chrysler System is identical to that described for Prestolite Rectifiers. See the Prestolite section.

Testing Stator

1. Disconnect rectifiers from stator leads.
2. Inspect stator connections.
3. Test from stator leads to stator core, using a 110-volt test lamp. If lamp lights stator is grounded, in which case replace stator.

Service Note

Excessive Ammeter Fluctuation

If this condition shows up, and is accompanied by flickering headlamps or inferior lights, it may be caused by high resistance in the field circuit to the alternator, or an improperly set voltage regulator.

To correctly diagnose this condition, disconnect the lead at the "IGN" terminal of the regulator. Connect a jumper lead from the positive post of the battery to the "IGN" terminal of the regulator. This will by-pass the car wiring harness circuit to the regulator.

Start and operate the engine at 1250 rpm and observe the lights and ammeter pointer. If the pointer is now normal and the lights do not flicker the cause of the fluctuation is corrosion or other high resistance in the field circuit, connectors or the "in-line" fuse holder.

Remove the jumper lead. Clean the connections and tighten the connectors if necessary. Tape the fuse holder completely to prevent moisture and dirt from entering the holder.

Fig. C6 Adjusting spring tension to obtain correct voltage

If the jumper lead did not correct the excessive ammeter fluctuation the regulator is improperly adjusted and should be corrected as outlined previously.

Excessive ammeter fluctuation should not be confused with the normal action of the regulator and ammeter in any car whether it has an alternator or D.C. generator in which the ammeter may normally show small irregular movements when the regulator just begins to regulate.

ALTERNATOR REPAIRS

Service Note

Whenever the alternator is disassembled for servicing, it is recommended that the two long rectifier-to-stator leads be located between the rectifiers in the heat sink and cemented to the rectifier end housing using weatherstrip adhesive. This is especially important if a replacement is made of an early type diode rectifier. The cementing of the leads will reduce vibration of the leads with resultant longer life of the rectifiers and leads.

Disassembly

To prevent possible damage to the brush assemblies, they should be removed before proceeding with the disassembly of the alternator. The insulated brush is mounted in a plastic holder that positions the brush vertically against one of the slip rings.

1. Remove the field terminal and related parts and lift the plastic holder containing the spring and brush from end housing, Fig. C7.
2. The ground brush is positioned horizontally against the remaining slip ring and is retained in a holder that is integral with the end housing. Remove the retaining screw and lift the clip, spring and brush from the end housing. *Stator is laminated; do not burr stator or end housings.*
3. Remove through bolts and pry between stator and drive end housing with a thin blade screwdriver. Care-

Fig. C7 Removing or installing insulated brush

Fig. C8 Removing pulley

Fig. C9 Removing bearing from rotor shaft

fully separate drive end housing, pulley and rotor from stator and rectifier housing.

4. Remove pulley with a puller, Fig. C8.
5. Remove three nuts and washers and, while supporting end frame, tap rotor shaft with a plastic hammer and separate rotor and end housing.
6. Remove drive end bearing with a puller, Fig. C9.
7. Remove D.C. output terminal screw and inside capacitor or condenser (on units so equipped), Fig. C10.
8. The heat sink, Fig. C11, is held in place by terminal screw.
9. Remove the insulator.
10. When removing the rectifiers, it is necessary to support the end housing and/or heat sink to prevent damage to these castings.
11. Refer to "Rectifier Testing," and if the rectifiers must be replaced, proceed as follows: Cut rectifier wire at point of crimp. Support rectifier housing on Tool C-3771. This tool is cutaway and slotted to fit over the wires and around the bosses in the housing. Make sure that the bore of the tool completely surrounds the rectifier, then press the rectifier out of the housing, using Tool SP-3380, Fig. C12.

Reassembly, Fig. C13

1. Check rectifier identification to make sure correct rectifier is being used. Identifying part numbers are stamped on the case of the rectifier. They may also be identified by paint marks: red for positive and black for negative.
2. Start new rectifier into case squarely and press rectifier into casting, Fig. C14.
3. Crimp new rectifier wire to wires disconnected at removal.
4. Press bearing into end housing.
5. Insert bearing in drive end housing and install bearing plate, washers and nuts to hold bearing in place.
6. Position bearing and drive end housing on rotor shaft and, while supporting the base of rotor shaft, press bearing and housing into position on rotor shaft, Figs. C15 and C16. Bearing must contact shoulder on rotor shaft.
7. Install pulley on rotor shaft, Fig. C17. Shaft of rotor must be supported in a manner so that all pressing force is on pulley hub and rotor shaft. Bearing should just contact bearing inner race, and bearing should contact shoulder on rotor shaft.
8. If alternator is equipped with an internal capacitor (condenser), make sure heat sink insulator is in place.
9. Install output terminal screw with capacitor attached through heat sink and end housing. Install insulating washers, lock-washers and lock nuts.
10. Position stator on rectifier end housing. Make sure that all of the rectifier connectors and phase leads will not interfere with rotor fans and

Fig. C10 Removing or installing inside capacitor

Fig. C11 Removing or installing heat sink insulator

Fig. C12 Removing a rectifier

that capacitor lead has clearance.

11. Position rotor in rectifier end housing and drive end housing. Align through-bolt holes in stator, rectifier end housing and drive end housing.
12. Enter shaft in rectifier end housing bearing. Compress stator and both end housings manually and install through-bolts, washers and nuts.
13. Install insulating brush and components as shown in Fig. C18. *If the nylon washer is advertently assembled between brush contact and field*

Fig. C13 Disassembled view of alternator

Fig. C17 Installing pulley

Fig. C14 Installing a rectifier

Fig. C16 Installing drive end housing and bearing on rotor shaft

Fig. C18 Installing insulating brush and related parts

Fig. C15 Installing rectifier end housing

terminal, battery current from voltage regulator will short circuit directly to ground through brush holder screw and end shield. This will result in a blown in-line fuse or internal fuse wire and may possibly damage voltage regulator.

14. Install ground brush and attaching screw, Fig. C19.
15. Rotate pulley slowly to make sure rotor fans do not hit rectifier and stator connectors.

Fig. C19 Installing ground brush

Delco-Remy "Delcotron"

DESCRIPTION

In these alternators, Figs. D1, D2, the rotor is mounted on ball bearings located in each end frame, and consists of multi-segmented north and south poles strengthened by field windings wound concentric with the rotor shaft. The field windings are energized by two brushes riding on slip rings pressed on the rotor shaft.

The stator windings are assembled on the inside of a laminated core that forms the Delcotron frame. Six rectifier diodes are mounted into two heat sinks located in the slip ring end frame. The diodes change the A.C. voltage to D.C. voltage which appears at the output terminal of the Delcotron.

Fig. D1 Aluminum Delcotron (5.5")

TESTING SYSTEM IN VEHICLE

Output Test

With ammeter and voltmeter hooked-up as shown in Fig. D3, slowly increase alternator speed and check rated output as given in Specifications Chart.

Caution: Load the battery with a carbon pile rheostat or turn on all lights and accessories to prevent high voltage. Do not allow alternator to exceed recommended voltage setting of regulator.

If alternator does not provide rated output, it should be removed for service as given further on.

Indicator Light & Relay Test

Turn on ignition switch, but do not start engine. If light does not come on, check for burned out bulb.

If the light comes on and continues to glow with the alternator operating at moderate speed, check the voltage from the regulator "R" terminal to ground with the alternator in operation, Fig. D4. If the reading is more than 5 volts, the indicator relay is defective. If the reading is 5 volts or less, trouble elsewhere in the system is indicated.

Undercharged Battery

An undercharged battery condition may be caused by one or more of the following factors:

1. Loose alternator drive belt.
2. Defective battery.
3. Malfunction of field relay. To check the field relay, connect a voltmeter from regulator "F" terminal to ground, Fig. D5. Turn on ignition switch but do not start engine. The voltmeter should read battery voltage. If it reads zero volts, the field relay contacts are not closed and the relay requires further attention.
4. Excessive circuit resistance. To check for this condition, connect a voltmeter from the insulated battery post to the field terminal on the alternator, Fig. D6. Turn on ignition switch but do not start engine. *Note: If alternator field terminal is not accessible, connect to regulator "F" terminal.*
   a. If reading exceeds 0.3 volts, excessive line resistance is indicated. Clean and tighten all connections at and between battery insulated post and regulator "V" terminal, and at regulator "F" terminal and alternator field terminal.
   b. If voltage reading still exceeds 0.3 volts, clean the alternator "Bat" terminal, field relay contacts and voltage regulator contacts.
   c. If the voltage reading still exceeds 0.3 volts, check the alternator for shorted or grounded fields. Remove lead from alternator field terminal and connect an ammeter in series with the field winding.
5. Defective alternator. Check output of alternator as outlined above.
6. Low voltage regulator setting. If no circuit defects are found, yet the battery remains undercharged, the cause most likely is a low voltage setting. Refer to "Tailoring the Voltage Setting".

Overcharged Battery

An overcharged battery may be caused by one or more of the following conditions:

1. Shorted battery cell.
2. Excessive circuit resistance. Check for this condition as covered under "Undercharged Battery".
3. High voltage regulator setting. If no circuit defects are found, yet the battery remains overcharged, refer to "Tailoring Voltage Setting".

Fig. D2 Perforated Stator Delcotron (6.2")

Fig. D3 Checking 5.5" alternator output

Fig. D4 Checking indicator light relay

Fig. D5 Checking field relay

Fig. D6 Checking circuit resistance

Voltage Setting

The voltage at which the regulator operates varies with changes in regulator ambient temperature (temperature of air ¼" from regulator cover). To check and adjust voltage setting, proceed as follows:

1. Make connections to system as shown in Fig. D7. The ¼ ohm resistor shown will limit the alternator output to 10 amperes or less which is required when checking and adjusting voltage setting.
2. Turn the variable resistor shown to the "no resistance" position.
3. Operate the alternator for 15 minutes at approximately 3000 rpm so that the regulator is operating on the upper set of contacts. *Leave cover on regulator to establish operating temperature.*
4. After the 15 minute warm-up period, cycle the alternator (turn off ignition and stop alternator.) Disconnect jumper lead from "V" to "Bat" terminals. *Caution: Turning the field rheostat connected at regulator "F" terminal will not cycle the alternator—leave rheostat in closed position.*
5. Reconnect jumper lead. Again run alternator at approximately 3000 rpm and note voltage reading (see Specifications Chart).
6. To adjust voltage while operating on the upper set of contacts, turn adjusting screw as shown in Fig. D8. *Caution: Always make final setting by turning screw clockwise. This insures that the spring holder will be against the screw head. After turning screw counterclockwise, pry holder up against screw head, then turn clockwise to make setting.*
7. After making setting, re-cycle the alternator. Then again operate alternator at about 3000 rpm and note voltage setting; readjust if necessary. *Note: Always cycle alternator before taking final voltage reading.*
8. After setting the voltage while operating on the upper set of contacts, check the setting while operating on the lower set of contacts as follows:
   a. Slowly increase the resistance of the variable resistor with the engine operating at 3000 rpm until the regulator begins to operate on the lower set of contacts. Note voltage reading and compare to those given in Specifications Chart. *Note: Turning the variable resistor does not cause the regulator to operate on the lower set of contacts. Return the variable resistor to the "no resistance" position. Turn the carbon pile to slightly load the battery, and adjust the variable resistor to cause the regulator to operate on the lower set of contacts.*

Fig. D7 Checking voltage setting

Fig. D9 Checking field relay closing voltage

Usually, turning on the headlights will substitute for the carbon pile.

9. The difference in voltage between the operation of the upper contacts and the lower set is increased by slightly increasing the air gap between the armature and center of core; voltage may be decreased by slightly decreasing the air gap. *Note: This setting may be made while the regulator is operating. It will be necessary to recheck the voltage setting of both contact sets if the air gap is changed.*

Tailoring The Voltage Setting

It is important to remember that voltage setting for one set of operating conditions may not be satisfactory for a different type of operating condition. Underhood temperature, operating speeds, and night time service are all factors which affect the proper voltage setting. The proper setting is obtained when the battery remains fully charged with a minimum use of water.

If no circuit defects are found, yet the battery remains undercharged, raise the setting by 0.3 volt. Then check the battery over a period of time to see if improvements were achieved. Reset regulator if necessary.

Field Relay Unit

1. To check the closing voltage of the field relay unit, make connections as shown in Fig. D9, using a 50-75 ohm variable resistor.
2. Turn resistor to open (maximum resistance) position.
3. Turn on ignition switch. *If oil pressure switch is used, temporarily place a jumper wire across terminals.*
4. Slowly decrease resistance and note closing voltage of relay. Adjust by bending heel iron, Fig. D10.

Indicator Light Relay Unit

1. To check the opening voltage of the indicator light relay, connect a 50-75 ohm variable resistor between the regulator "V" and "R" terminals.
2. Turn resistor to open (maximum resistance) position.
3. Connect a voltmeter from the regulator "R" terminal to ground (see Fig. D4).
4. Slowly decrease resistance and note the opening voltage. Adjust by bending heel iron as shown in Fig. D10.

Fig. D8 Adjusting voltage setting

BENCH TESTS

Fig. D10A is a convenient chart for making bench tests on Delcotrons. Due to the ease of stator removal in the flat heat sink 5.5" units, it is advisable to remove the stator before making any stator or diode electrical tests. To remove the stator, remove all three stator lead attaching nuts, then separate the stator from the end frame. The fit between the stator and end frame is not tight so the two should be easy to separate by hand. After the stator is removed, the electrical tests are identical on both the flat heat sink and "Gull Wing" heat sink units.

The operations described below are for both types of alternators, Figs. D11 and D12. Where important differences in testing are encountered, separate mention will be made of the two alternators. Remove and disassemble the alternator as outlined later on. Then proceed with the tests as follows:

Testing Rotor

The rotor may be tested electrically with a 110-volt test lamp or with an ohmmeter.

To check for grounds, connect test lamp or ohmmeter from either slip ring to the rotor shaft or to the rotor poles. If the lamp lights or if the ohmmeter reading is low, the field windings are grounded, Fig. D13.

To check for open circuits, connect the test lamp or ohmmeter to each slip ring. If the lamp fails to light or if the ohmmeter reading is high, the windings are open.

For short circuits, the windings are checked by connecting a battery and ammeter in series with the two slip rings. An ammeter reading above 1.5 amperes indicates shorted windings. An alternate method is to check the resistance of the

Fig. D10 Adjusting field relay unit

Fig. D13 Checking rotor for grounds and open circuits

COMPONENT	TEST CONNECTION	NORMAL READING	IF READING WAS	TROUBLE IS
ROTOR	Ohmmeter from slip ring to rotor shaft	Infinite resistance	Very low	Grounded
	110 volt test lamp from slip ring to shaft	No light	Lamp lights	Grounded
	Ohmmeter across slip rings	5.5" units—5 to 7 ohms 6.2" unit—7 to 9 ohms	Very high	Open
			Very low	Shorted
	110 volt test lamp across slip rings	Lamp lights	No light	Open
	12 volt battery thru ammeter to slip rings	5.5" units—2.2 amps. 6.2" unit—1.5 amps.	High	Shorted
			Low	Open
STATOR	Ohmmeter from stator lead to frame	Infinite resistance	Very low	Grounded
	110 volt test lamp from lead to frame	No light	Lamp lights	Grounded
	Ohmmeter across each pair of leads	Less than ½ ohm	Any reading very high	Open
	110 volt test light across each pair of leads	Lamp lights	No light	Open
DIODES	Ohmmeter across diode, then reverse connections	A low meter reading one way, near infinite reading the other	Both readings very low	Shorted
			Both readings very high	Open
	12 volt test lamp across diode, then reverse connections	Lamp should light one way, and not the other	Lamp fails to light in both checks	Open
			Lamp lights in both checks	Shorted

Fig. D10A Delcotron bench tests

field by connecting an ohmmeter to the two slip rings, Fig. D13. If resistance is below 6 ohms the winding is shorted.

Testing Stator

To test for grounds, connect a 110-volt test lamp or an ohmmeter from any stator lead to the stator frame. If test lamp lights or if ohmmeter reads low, the windings are grounded, Figs. D14, D15.

To test for open circuits, if lamp fails to light or if ohmmeter reads high when successively connected between each pair of stator leads, the windings are open, Figs. D14, D15.

A short in the stator windings is difficult to locate without special test equipment due to the low resistance of the windings. However, if all other electrical checks are normal and the alternator fails to supply rated output, shorted stator windings are indicated.

Testing Diode Rectifiers

An ohmmeter or a 12-volt test lamp may be used to check diodes for shorts or opens. *Caution: Do not use a 110-volt test lamp to test diodes.*

Ohmmeter Method

1. Use an ohmmeter with a 1½ volt cell and use the lowest range scale.
2. With the stator disconnected, check a diode in the heat sink by connecting one of the ohmmeter leads to the heat sink and the other lead to the diode lead and note the reading, Figs. D16, D17.
3. Reverse the ohmmeter leads and note the reading.
4. If both readings are very low, or if both readings are very high, the diode is defective. *A good diode will give one low reading and one high reading.*
5. Check the other two diodes in the heat sink in the same manner.
6. To check a diode mounted in the end frame, connect one of the ohmmeter leads to the end frame and the other

Fig. D11 Aluminum Delcotron (5/5")

Fig. D12 Perforated Stator Delcotron (6.2")

Fig. D14 Checking 6.2" stator for grounds and opens

lead to the diode lead, Figs. D16, D17.

7. Note the reading. Then reverse the ohmmeter lead connections and note the reading. Interpret readings as mentioned in Step 4.

Test Lamp Method—Check as above with a 12-volt test lamp. When checking a diode, the lamp will light in only one of the diode checks. If lamp lights when checked in both directions, the diode is defective.

DELCOTRON REPAIRS

Service operations described below are for both type alternators. Where important differences are encountered, separate mention will be made of the two alternators.

Fig. D15 Checking 5.5" stator for grounds and opens

Removal

Caution: Disconnect battery ground strap to prevent accidentally reversing the polarity of the system and damaging the diode rectifiers.

1. Disconnect "Bat", "Relay" and "Grd" leads from alternator terminals, and harness connector from field terminals at brush holder.
2. Remove alternator brace bolt, detach fan belt and lower alternator.
3. Remove bracket bolt or bolts and remove alternator from vehicle.

Disassembly

1. Remove through bolts and separate drive end frame and rotor assembly by prying apart at stator slot. Note that the separation is to be made between the stator frame and drive end frame.
2. After disassembling, place a piece of tape over the slip ring end frame bearing to prevent entry of dirt. *Caution: Brushes may drop onto rotor shaft and become contaminated with bearing lubricant. Clean brushes prior to installation with a non-toxic cleaner.*
3. Separate rotor from drive end frame.
4. Remove drive end frame bearing by removing retainer plate screws and separating retainer plate from end frame.
5. Remove slip ring brush holder from end frame.
6. Separate stator assembly and end frame by first cutting three diode connectors just below the crimp mark, Fig. D18. If the connectors are full of solder, melt the solder and then remove connectors with pliers. Cut diode leads as close as possible on the 6.2" Delcotron. Separate stator frame from end frame. *Note: On the 6.2" Delcotron, note carefully the stator lead locations, and the location of the heat sinks with respect to the end frame locating notch on the shell. Also note carefully the proper position of the output terminal and the insulating washers used on the heat sink. Caution: Do not move diode stems excessively or internal damage to diode may result.*

Inspection

1. Wash all metal parts except stator and rotor assemblies.
2. Clean and inspect bearings.
3. Inspect rotor slip rings. They may be cleaned with 400 grain polishing cloth. Rotate rotor for this operation to prevent creating flat spots on slip rings.
4. Slip rings that are out of round may be trued in a lathe to .001" maximum indicator reading. Remove only enough material to make the rings smooth and concentric. Finish with 400 grain polishing cloth and blow dry.
5. Perform bench tests of units as already described.

Diodes, Replace

In order to avoid damage to the heat sink and the diode being installed, it is recommended that the tools shown in Fig. D19 be used when replacing diodes.

Fig. D16 Checking 6.2" Delcotron diode rectifiers

Fig. D17 Checking 5.5" Delcotron diode rectifiers

Fig. D18 Cutting diode connectors (5.5" Delcotron)

Fig. D19 Diode service tools

These tools are available from various suppliers, among which are the Kent-Moore Organization, Inc., Warren, Mich.

Negative case diodes have black markings on the case, and positive case diodes have red markings on the case. Inspect the diodes for color markings, Fig. D20, and note that the heat sink connected to the alternator output terminal is insulated from the shell, and the other heat sink is grounded to the shell.

When replacing diodes in the 5.5" Delcotron with "Gull Wing" heat sink, the heat sink must be removed from the end frame and properly supported for diode press operations. When replacing diodes in the 6.2" Delcotron or in the 5.5" unit with the flat heat sink, the heat sink must be properly supported for press operations, regardless of whether the heat sink is removed or left installed in the shell or end frame.

1. To replace a defective diode on the 5.5" Gull Wing Delcotron, cut the diode and stator leads at all diode tubular connectors. On the 6.2 Delcotron, if the diode is to be replaced without removing the heat sink, cut the leads only at the diode being replaced. All diode and stator leads on the 5.5" unit with flat heat sink are provided with eyelet terminals.
2. Remove the 5.5" Gull Wing heat sink from the end frame by removing the "BAT" and "GRD" terminal screws. On 5.5" units with flat heat sink, if the heat sink is to be removed for diode replacement, remove the screw from the condenser lead also.
3. To remove diodes from both 5.5" and 6.2" units, use the appropriate tool to support the heat sink or end frame at the terminal side of the diode while pressing out the diode. Use an arbor press or large bench vise for the press operation. *Do not attempt to remove a diode by striking the assembly as the shock may damage good diodes that are installed.*
4. To install a new diode, support the underside of the heat sink on a suitable flat surface. Press the new diode into place, using an installer that has a special shoulder to accept the diode.
5. When connecting a 5.5" Gull Wing or a 6.2" Delcotron replacement diode in the circuit, insert the stator and diode leads into the special tubular connector. Using pliers, crimp the connector only tight enough to hold the leads for soldering. *Crimping the connector lightly will permit its later removal, if necessary, without further shortening the leads.* Establish a good electrical connection by filling the connector with rosin core solder. *To be sure that the diode is not damaged by heat during soldering, reduce heat transfer to the diode by clamping pliers on the diode lead.*

Delcotron Condenser

The condenser (or capacitor) attached to the Delcotron rear end frame is not primarily used for radio suppression although it does help in this respect. The unit's main job is to protect the positive diodes from surges of transient voltage produced during operation of the Delcotron.

Since the condenser is rated at only 5 microfarads, it is impractical to test the capacitance with conventional equipment. However, the unit must be tested for a short to ground. This test can be made with a 1.5 volt ohmmeter or a 12 volt test light. Connect one test lead to the condenser lead and the second test lead to the case. Wiggle the condenser "pig tail" lead. The ohmmeter should show infinite resistance or the light should not glow throughout the test. Any condenser that allows current leakage, as indicated by a low meter reading or a glowing test lamp, must be replaced. The "Gull Wing's" version condenser bracket is retained to the end frame by a machine screw. Simply remove this screw to install a new condenser.

Replacement of the flat heat sink unit's condenser involves a press operation. The condenser is retained in the bore by a spring steel retainer with both external and internal teeth. Since the retainer is countersunk, the condenser must be pressed from inside the end frame or pig tail end of the condenser for both removal and replacement. A shouldered diode installing tool or its equivalent may be used for pressing the condenser. Use care to avoid damaging the condenser case. Do not drive the condenser in or out of the end frame as the shock may damage the diodes. Always test the new condsenser after installation.

If the Delcotron has experienced repeated diode failure, replace the condenser. The possibility that a faulty condenser caused the diode failure is very slight, but a new one is good insurance.

Fig. D20 Removing and installing diode rectifiers

Fig. D22 Three unit double contact regulator used on vehicles having an indicator light instead of an ammeter

Fig. D23 Two unit double contact regulator used on vehicles having an ammeter instead of an indicator light

Fig. D24 Adjusting voltage regulator point opening

Brushes, Replace

After removing brush holder, inspect brushes for wear. If they are worn halfway, they should be replaced. Inspect brush springs for discoloration or weakening. If brushes appear satisfactory and move freely in brush holder, springs may be re-used.

5.5" Delcotron

1. Remove heat sink.
2. Attach brush holder to end frame and insert pin or wire through hole, Fig. D21, to hold brushes in holder.
3. After unit has been completely assembled, withdraw pin or wire to allow brushes to drop down onto slip rings.
4. Replace heat sink, following carefully the proper stack-up of parts.

6.2" Delcotron

1. Remove brush holder and capacitor from slip ring end frame.
2. Install new brushes by pushing brushes up into holder and looping the brush leads over the catcher to keep the brushes in the holder.
3. Attach the assembly to the end frame and lift the brush leads off the catcher to allow brushes to ride on the slip rings.

Delcotron, Assemble

1. Install stator in slip ring end frame and locate connectors over relay, diode and stator leads.
2. Crimp leads with pliers only tight enough to hold connector onto leads. This will permit removal of connector later on if necessary.
3. Fill connectors with rosin core 60% tin 40% lead solder. *Caution: Do not use excessive heat for this operation, and carefully inspect to make sure no solder has run down onto diode.*
4. Position rotor and drive end frame into slip ring end frame and stator. Install and tighten through bolts.
5. Install brush holder on slip ring end frame, where necessary.

DOUBLE CONTACT REGULATORS

Figs. D22, D23 illustrate the two types of voltage regulators commonly used with "Delcotron" alternators. While most regulator adjustments are made on the vehicle as outlined under Testing System In Vehicle, the regulator must be removed for point cleaning and air gap adjustment.

To remove the regulator, disconnect the leads at the regulator terminals and remove the screws securing the unit to the vehicle. *Caution: Disconnect battery ground terminal to prevent accidently grounding leads from regulator and causing damage to the diode rectifiers.*

Electrical settings must be checked and adjusted after making the mechanical adjustments described below. Before installing regulator cover, make sure rubber gasket is in place on regulator base.

The contacts on the voltage regulator unit are of a soft material and must not be cleaned with a file. They may be cleaned with crocus cloth or other fine abrasive material, and should then be washed with a non-toxic solvent to remove any residue. To clean field relay and indicator light relay contacts, use a thin, fine-cut, flat file. Remove only enough material to clean the points. *Never use emery cloth or sandpaper to clean contact points.*

Voltage Regulator Unit

Point Opening—With lower contacts touching, measure point opening between upper contacts as shown in Fig. D24. Adjust by bending upper contact arm.

Air Gap—Measure air gap between armature and core with lower contacts touching, Fig. D25. To adjust, loosen contact support bracket screw about 1/8 to 1/4 turn. Place screwdriver in slot in contact support bracket and into the molded insulator (see Fig. D28). Raise screwdriver handle to increase the air gap and lower the handle to lower air gap.

Field Relay Unit

Point Opening—Point opening is checked as illustrated in Fig. D26. If adjustment is required, carefully bend flat contact support spring.

Air Gap—Check the air gap with the points just touching, Fig. D27. If the point opening and closing voltages are within specifications, the relay will operate satisfactorily even though the air gap may not be exactly according to specifications. Normally, the air gap need not be adjusted.

Indicator Light Relay Unit

Air gap is the only mechanical adjustment required on this unit. Hold the armature down against a gauge of the specified thickness. The contacts should barely touch. If they do not, adjust by bending upper contact support, Fig. D28.

Regulator, Install

1. Make sure attaching area is clean for proper ground, then install regulator and tighten mounting screws. *Caution: Do not tighten screws excessively as this will destroy the cushioning effect of the rubber grommets in the mounting.*
2. Attach regulator leads to proper

Fig. D25 Adjusting voltage regulator air gap

Fig. D26 Checking field relay point opening

Fig. D27 Checking field relay air gap

Fig. D28 Adjusting indicator light relay air gap

terminals. *Caution: Do not polarize the alternator.*

3. Connect battery ground terminal.
4. Check and adjust electrical settings as covered under Testing System In Vehicle.

DELCO-REMY TRANSISTORIZED REGULATORS

The four-terminal regulator shown in Fig. D29 is used in circuits with an ammeter. Note that this assembly contains a vibrating voltage regulator unit and a field relay unit.

A three-terminal regulator is used in circuits with either an ammeter or an indicator light. This assembly contains a vibrating voltage regulator and an indicator light relay unit.

Each type of regulator uses a single transistor and a diode. The transistor works in conjunction with the conventional voltage regulator having a vibrating contact point to limit the alternator voltage to a pre-set value. Because of its ability to permit current to flow in one direction but not in the other, the diode reduces arcing at the voltage regulator contacts by dissipating the energy created in the alternator field windings when the contacts separate.

Greater alternator field current and smaller voltage regulator contact point current both result from the use of a transistor. This improves alternator performance and lengthens contact point life.

Four-Terminal Type

An ammeter is used in the charging circuit with this type regulator. *Caution: Do not short across F-1 and F-2 terminals on the regulator and alternator. Do not attempt to polarize the alternator.*

Voltage Regulator Air Gap

With the regulator removed from the

Fig. D29 Delco-Remy transistorized regulator of the four-terminal type used when vehicle has an ammeter

Fig. D30 Adjusting voltage regulator air gap

vehicle, the air gap may be adjusted as shown in Fig. D30. Push the armature down against the wire gauge and adjust the upper contact support so that the contacts are aligned squarely and just touch when the contact support screws are tightened.

Voltage Setting

The voltage at which the regulator operates varies with changes in regulator ambient temperature. The ambient temperature is the temperature of the air measured with a thermometer ¼" from the regulator cover.

Fig. D31 will aid in making the desired voltage setting. To check and adjust the voltage setting, proceed as follows:

1. Make connections as shown in Fig. D32.
2. With ignition switch on, operate alternator at 3000 rpm for 15 minutes with 3 to 10 amperes output. Use a ¼-ohm resistor in series *between battery and junction block* if necessary to reduce output to 10 amperes or less. Leave cover on regulator.
3. After the 15 minute warm-up period, cycle the alternator by turning off the ignition switch and stopping the

REGULATOR AMBIENT TEMPERATURE	VOLTAGE			
145°F	12.7	12.9	13.1	13.3

alternator; then re-run alternator at 3000 rpm and note voltage setting.

4. To adjust voltage setting, remove cover and turn screw on back of regulator as shown in Fig. D33. *Caution: Always make final setting by turning screw clockwise. This insures that the spring holder will be against the head of the screw. After turning screw counterclockwise, pry holder up against screw head, then turn clockwise to make setting.*
5. After making setting, cycle the alternator by turning off the ignition switch and stopping the alternator.
6. Turn on ignition switch, operate alternator at 3000 rpm and note voltage setting. Readjust if necessary,
7. Always cycle the generator before reading the final voltage setting on the voltmeter. When decreasing the voltage setting, the alternator output may decrease to the 3 amperes minimum allowable, or even to no output. If this happens, load the battery with a carbon pile rheostat connected across its posts, or turn on electrical accessories in order to obtain the 3 to 10 amperes alternator output when adjusting the voltage setting.

Field Relay Unit

Air-Gap—With the regulator removed from the vehicle, check the air gap with the points just touching as shown in Fig. D34. The air gap normally need not be adjusted. If the point opening and closing voltage are within specifications, the relay will operate satisfactorily even though the air gap may not be exactly according to specifications.

Point Opening — The point opening is checked as shown in Fig. D35. If adjustment is necessary, carefully bend the flat contact spring support.

Closing Voltage—The closing voltage of the field relay should be checked immediately after the voltage regulator setting check, before the unit has had time to cool off. Check closing voltage as follows:

1. Make connections as shown in Fig. D36, using a 50 ohm variable resistor.
2. Turn resistor to "open" position.
3. Turn ignition switch on.
4. Slowly decrease resistance and note closing voltage of relay. Adjust by bending heel iron.

Three Terminal Type

Caution: Do not short across F and Bat terminals on the regulator, or F-1 and F-2 terminals on alternator. Do not attempt to polarize alternator.

Voltage Regulator Unit

The air gap and voltage settings are made the same as outlined for the four-terminal regulator. To check the voltage setting, connect the ammeter in the circuit at the "BAT" terminal of the alternator, and the voltmeter from the "BAT" terminal of the regulator to the regulator base, Fig. D37. Adjust as shown in Fig. D33.

Fig. D38 Checking closing voltage setting of indicator light relay on three-terminal regulator

Fig. D41 Checking closing and sealing voltage of field relay

Fig. D39 Field relay air gap adjustment

Fig. D40 Field relay point opening adjustment

Fig. D42 Adjusting field relay closing voltage

Indicator Light Relay Unit

Air Gap—The air gap is checked and adjusted in the same manner as outlined for the four-terminal regulator unit (see Fig. D30).

Closing Voltage—This check must be made immediately after the voltage regulator setting check, before the regulator has had time to cool off.

1. Make connections as shown in Fig. D38, using a 50 ohm variable resistor. *Do not operate alternator with resistor in the circuit.*
2. Turn resistor to "off" position.
3. Turn ignition switch on. The battery must be sufficiently charged to cause the contacts to open at the "off" position of the resistor.
4. Slowly increase resistance and note voltage at which contacts close.
5. Adjustment procedure is identical to that of the four-terminal regulator (see Fig. D33).

Separately Mounted Field Relay

Air Gap—Check the air gap as shown in Fig. D39. Push the upper contact down until points just touch, and adjust the air gap between armature and core by bending lower contact support.

Point Opening — The point opening is checked and adjusted as shown in Fig. D40. To adjust, bend armature stop with suitable bending tool.

Closing Voltage—Make connections as shown in Fig. D41. Then proceed as follows:

1. Turn resistor to "open" position.
2. Turn on ignition switch.
3. Slowly decrease resistance and note voltage at which points just close.
4. To adjust, bend armature spring, post, Fig. D42.

Sealing Votlage—After points have just closed in the closing voltage check above, continue to decrease the resistance and not the voltage at which armature seals to the core. To adjust, slightly decrease the air gap by bending the lower contact support. *Remember to adjust point opening after changing the air gap.*

FORD ALTERNATORS

TESTING SYSTEM IN VEHICLE

Alternator Output Test

1. Make connections as shown in Fig. F2. Be sure that the Generator Field Control is in the "open" position at the start of this test.
2. Close the battery adapter switch. Start the engine, then open the battery adapter switch. *All electrical accessories, including door operated interior lights must be turned off.*
3. Carefully increase engine speed to a tachometer reading of 2900 rpm. *Do not exceed this speed.*
4. Adjust the Generator Field Control until the voltmeter reads exactly 15 volts. Observe the ammeter reading. Add 5 amperes to this reading to obtain total alternator output. The 5-ampere factor represents the field current and the ignition system current, and must be added to the ammeter reading as these currents are not indicated on the ammeter. *Make this test in the shortest possible time and do not exceed 2900 rpm. If the battery was fully charged, it might not be possible to obtain maximum current output. If specified current is not obtained, make the following test before condemning the alternator.*
5. Turn the Generator Field Control to the "open" position. Rotate the tester control knob to the "load" position. Maintain 2900 rpm engine speed.
6. Adjust the Generator Field Control and the "load" control, maintaining a voltmeter reading of 15 volts maximum, until the Generator Field Control is at its maximum clockwise position.
7. Readjust the "load" control until the voltmeter reads exactly 15 volts. Observe the ammeter reading. Add 5 amperes to this reading to obtain total alternator output.
8. Stop the engine, return the Generator Field Control to the "open" position and disconnect the test equipment.

Test Analysis

1. An output of 2 to 5 amperes below specifications indicates an open diode rectifier. An output of approximately 10 amperes below specifications indicates a shorted diode rectifier. *An alternator with a shorted diode will usually whine, which will be noticeable at idling speed.*
2. A shorted *positive* diode may sometimes be accompanied by alternate flashing of the oil pressure and charge indicator lights when the ignition switch is off. The field relay contacts will also be closed and the battery will be discharging through the field to ground.
3. Under this condition, the instrument constant voltage regulator will receive power through the charge indicator light. The operating of the constant voltage through the charge indicator light causes the alternate flashing of the lights. When the regulator contacts close, the oil pressure light becomes dim and the charge indicator light becomes bright. When the contacts open the oil pressure light becomes bright and the charge indicator light becomes dim.

Fig. F1 Ford alternator wiring diagram

Diode Test

1. To test the positive diodes, make connections shown in Fig. F3. Connect the probe to each diode lead. Make sure that the tip of the probe is sharp and that it penetrates the varnish at the diode terminal.
2. To test the negative diodes, make the connections shown in Fig. F4. Follow the same procedure as for positive diodes.
3. Good diodes will be indicated as on the meter in Figs. F3 and F4, that is, 2 amperes or more and readings alike within 2 scale divisions.

Field Open or Short Circuit Test

1. Make connections as shown in Fig. F5. The normal current draw, as indicated by the ammeter, should be as specified in the *Alternator and Regulator Specifications* chart in the truck chapters.
2. If there is little or no current flow, the field has a high resistance or is open, or the brushes are not making proper contact with the slip rings.
3. A current flow considerably higher than that specified (usually 2.9 to 3.1 at 12 volts) indicates shorted or grounded turns.
4. If the test shows that the field is shorted, *and the field brush assembly is not at fault,* the entire rotor must be replaced.

Field Relay Supply Voltage Test

The regulator field relay will close only if the voltage supplied by the neutral terminal of the alternator is sufficient to operate the relay. The wiring from the alternator neutral terminal to the relay "S" terminal also must be intact. The following test will show that both sufficient voltage is available and that the wiring is in good condition.

1. Remove the connector plug from the regulator, remove the regulator, then reinstall the connector plug.
2. Connect the negative voltmeter lead to ground. Start the engine and operate it at 400 to 500 rpm.
3. Connect the positive voltmeter lead to a small screwdriver. Touch the screwdriver to the center rivet at the front of the regulator. *Use care to touch only the rivet or the rivet terminal so as not to short this point to ground or to the other nearby terminals.* The voltmeter should indicate at least 6 volts, and the relay contacts should be closed.
4. Low voltage at this point can be caused by a defective alternator or defective wiring.

Fig. F2 Alternator output test

Fig. F3 Positive diode test

REGULATOR TESTS

The following tests are to be made with the regulator in the vehicle. Be sure that the regulator is at "normal" operating temperature. This is equivalent to the temperature after 20 minutes of operation with a 10-ampere load.

Field Relay Test

1. Disconnect regulator terminal plug and remove the regulator cover.
2. Make connections shown in Fig. F6.
3. Slowly rotate field resistance control clockwise from the off position until the field relay contacts close.
4. Observe the voltmeter reading at the moment that the relay closes. This is the relay closing voltage.
5. If the relay closes immediately, even with the field resistance close to the "off" position, use a 6 volt battery for this test.
6. If the closing voltage is not within specifications, adjust the relay.

Voltage Limiter Test

For test purposes, the lower stage regulation is used (armature vibrating of the lower contact). Voltage limiter calibration test must be made with the regulator cover in place and the regulator at "normal" operating temperature (equivalent to temperature after 20 minutes of operation with a 10-ampere load).

1. Make test connections shown in Fig. F7.
2. Turn off all accessories, including door-operated dome lights.
3. Close battery adapter switch, start engine, then open adapter switch.
4. Attach the voltage regulation thermometer to regulator cover.
5. Operate engine at 200 rpm for 5 minutes. Turn master control to "direct" position.
6. If the ammeter indicates more than 10 amperes, remove battery cables and charge the battery.
7. When battery is fully charged, and the voltage regulator has been temperature stabilized, rotate the master control to the "Voltage Reg." position, the ammeter should indicate less than 2 amperes.
8. Cycle the regulator as follows: Stop engine, close adapter switch, start engine, and open adapter switch.
9. Allow battery to normalize for a short time, then read the voltmeter.
10. Read the thermometer, and compare the voltmeter reading with the voltage given in Fig. F8.
11. If the regulated voltage is not within specifications, make a voltage limiter adjustment. *After each adjustment, be sure to cycle the regulator before each reading. Readings must be made with cover in place.*

Circuit Resistance Test

For the purpose of this test, the resistance values of the circuits have been converted to voltage drop readings for a curent flow of 20 amperes.

Alternator to Battery Positive Terminal

1. Make connections shown in Fig. F9.
2. Turn off all lights and electrical accessories.
3. Close battery adapter switch, start engine, then open battery adapter switch.
4. Slowly increase engine speed until ammeter reads 20 amperes.
5. Voltage should be no greater than 0.3 volts.

Fig. F4 Negative diode test

Fig. F5 Field open or short circuit test

Alternator to Battery Ground Terminal

1. Make connections shown in Fig. F10.
2. Close battery adapter switch, start engine and open battery adapter switch.
3. Slowly increase engine speed until ammeter reads 20 amperes.
4. Voltage indicated should be less than 0.1 volt.

REGULATOR ADJUSTMENTS

Erratic operation of the regulator, indicated by erratic movement of the voltmeter during a voltage limiter test, may be caused by dirty or pitted regulator contacts.

Use a very fine abrasive paper such as silicone carbide, 400 grade, to clean the contacts. Wear off the sharp edges of the abrasive by rubbing against another piece of abrasive paper. Fold the abrasive paper over and pull it through the contacts to clean them. Keep all oil or grease from contacting the points. *Do not use compressed air to clean the regulator. When adjusting the gap spacing, use only hospital clean feeler gauges.*

Regulator Bench Adjustments

The difference between the upper stage and lower stage regulation (0.3 volt), is determined by voltage limiter point and core gaps.

Adjust point gap first. Referring to Fig. F11, loosen the left side lock screw ¼ turn. Use a screwdriver blade in the adjustment slot above the lock screw. Adjust the upper contact until there is .010 to .015″ gap between lower contacts. Tighten lock screw and recheck the gap.

To adjust the core gap, loosen the center lockscrew ¼ turn. Use a screwdriver blade in the slot under the lock screw. Adjust the core gap to .045 to .052″ clearance between armature and core at edge of core closest to contact points. Tighten lock screw and recheck core gap.

Regulator Voltage Adjustments

Final adjustment of the regulator must be made with the regulator at operating temperature.

The field relay closing voltage is adjusted by bending the spring arm, Fig. F11. To increase the closing voltage, bend the spring arm down. To decrease the closing voltage, bend the spring arm up.

The voltage limit is adjusted by bending the voltage limiter spring arm, Fig. F11. To increase the voltage bend the adjusting arm downward. To decrease the setting, bend the adjusting arm upward.

Before setting the voltage and before making a final voltage test, the alternator speed must be reduced to zero and the ignition switch opened momentarily to cycle the regulator.

ALTERNATOR REPAIRS

Disassembly

1. Mark both end housings with a scribe mark for reassembly. Reach through a ventilation slot, raise both brushes off slip rings and install a short length of ⅛″ rod or stiff wire through hole in rear end housing, Fig. F12, to hold brushes off slip rings.
2. Remove 3 housing through bolts and separate front housing and rotor from rear housing and stator. *Make certain that brushes do not contact the greasy rotor shaft.*
3. Remove nuts from rectifier-to-rear housing studs and remove rear hous-

Fig. F6 Field relay test

Fig. F7 Voltage limiter test

ing. Remove two spacer sleeves from rectifier plate studs.

4. Press bearing from rear end housing, Fig. F13.
5. Remove terminal spacer block from studs and unsolder neutral wire from spacer block neutral terminal.
6. If brushes are being replaced, straighten field brush, terminal blade locking tabs with a pair of pliers and remove terminal blade from terminal spacer block assembly. Remove brushes and holders.
7. If either diode plate is being replaced, carefully unsolder leads from diodes, Fig. F14. Use only a 100 watt soldering iron. Leave the soldering iron in contact with the diode terminals only long enough to remove the wires. Both pliers are used as temporary heat sinks in order to protect diodes. *Excessive heat can damage a good diode.*
8. Remove 3 insulated diode plate screws and insulators, and separate diode plates.
9. Remove drive pulley, Fig. F15.
10. Remove 3 screws that hold front bearing retainer and remove front housing.
11. If the bearing is being replaced, remove it as shown in Fig. F16. Remove bearing retainer and spacer. It will not be necessary to remove the stop ring unless it has been damaged.

Inspection

1. The rotor, stator, diodes and bearings are not to be cleaned with solvents. These parts are to be wiped off with a clean cloth. Cleaning solvent may cause damage to electrical parts or contaminate the bearing internal lubricant. Wash all other parts with solvent and dry them.

Voltage Regulation Setting (Volts)	Ambient Air Temperature °F
14.3-15.1	50
14.1-14.9	75
13.9-14.7	100
13.8-14.6	125
13.6-14.4	150
13.5-14.3	175

Fig. F8 Voltage regulation and ambient air temperature factors

2. Rotate front bearing on drive shaft. Check for any scraping noise, looseness or roughness that would indicate that the bearing is excessively worn. As the bearing is being rotated, look for any lubricant leakage. If any of these conditions exist, replace the bearing.
3. Place the rear end bearing on the slip ring end of the shaft and rotate the bearing on the shaft. Make the same check for wear or damage as for the front bearing.
4. Check the housings for cracks. Check the front housing for stripped threads in the mounting holes. Replace defective housings.
5. Pulleys that have been removed and installed several times may have to be replaced because of the increased bore diameter. A pulley is not suitable for reuse if more than ¼ of the shaft length will enter the pulley bore with light pressure. Replace any pulley that is bent out of shape. After installing the pulley, check for clearance between the fins and the alternator drive end housing.
6. Check all wire leads on both stator and rotor for loose soldered con-

Fig. F9 Voltage drop test from alternator to battery positive terminal

Fig. F15 Removing pulley

Fig. F16 Removing front bearing

Fig. F17 Slip ring runout check

Fig. F18 Installing pulley

Fig. F19 Stator, heat sink and terminal spacer block assembly

Fig. F20 Brushes retracted for assembly

nections and for burned insulation. Resolder poor connections and replace parts that show burned insulation.

7. Check slip rings for damaged insulation. Check the slip rings for runout as shown in Fig. F17. If the slip rings are more than .0005″ out of round, take a light cut (minimum diameter limit ½″) from the face of the rings to true them up. If the slip rings are badly damaged, the entire rotor will have to be replaced as they are serviced only as a complete assembly.
8. Replace the terminal spacer block assembly if the neutral terminal is loose. Replace any parts that are burned or cracked. Replace brushes that are worn to less than .350″ in length. Replace the brush spring if it has less than 7 to 12 ounces tension.

Assembly

1. If the stop ring on the drive shaft was broken, install a new stop ring. Push the new ring on the shaft and into the groove. *Do not open the ring with snap ring pliers.*
2. Position the front bearing spacer on the drive shaft against the stop

ring, and position the bearing retainer on the shaft with the flat surface of the retainer outward.

3. Putting pressure on the inner race only, press the new bearing on the shaft until it contacts the spacer.
4. Place the front housing over the shaft with the bearing positioned in the front housing cavity. Install the bearing retainer mounting screws.
5. Press the pulley onto the shaft until the hub just touches the inner race of the front bearing. Fig. 18. *A new pulley must be installed if more than ¼ of the shaft length will enter the old pulley bore with light pressure.*
6. If a new diode plate is being installed, mount the two plates together so that they are insulated from each other, Fig. F19. Solder the wire leads to the diodes as shown in Fig. F14, using only a 100 watt iron. *Avoid excessive heat as this can result to damage to the diode.*
7. Insert the new field brush terminal blade into the slot in the terminal spacer block with the brush pigtail extending toward the brush holder pivots, Fig. F19.
8. Install brush holders and brush spring to terminal block, then position brushes in holders.
9. Solder the neutral wire to its terminal. Position terminal spacer block on rectifier plate mounting studs, with the ground brush lug over the mounting stud farthest from the output terminal, Fig. F19.
10. Place spacers on rectifier mounting studs farthest from terminal block.
11. Install rear bearing so that its open end is flush with the inner surface of the housing boss, Fig. F13. Allow for space under the outer end of the bearing during installation.
12. Place rear end housing over rectifier plate and stator assembly and mount rectifier plates to housing.
13. Retract brushes and insert a short piece of ⅛" rod or stiff wire through hole in rear end housing to hold brushes in retracted position, Fig. F20.
14. Wipe clean the rear bearing surface of the rotor shaft.
15. Position rear housing and stator assembly over rotor and, after aligning marks made during disassembly, install housing through bolts. Remove brush retracting rod.

Leece-Neville System

SERIES 6000

The two-element regulator used with these alternators consists of a voltage regulator and a load relay which is connected to the auxiliary terminal on the ignition switch, Fig. L1. The load relay, controlled by the ignition switch, functions as a reverse current relay. When the ignition switch is turned on, the relay contacts close to energize the field coil in the alternator.

Fig. L1 Wiring hook-up of Leece-Neville 6000 Series alternator system

TESTING SYSTEM IN VEHICLE

With the engine at idle speed, remove the "F" lead from the alternator and attach a jumper wire from the "F" terminal to the "B" terminal. This jumper connection will take the regulator out of the circuit and allow the alternator to operate at full field strength.

If the alternator shows a high rate of charge when running with full field strength, the alternator is functioning and the problem lies with the regulator, system wiring or battery.

If the alternator shows a very low or no rate of charge when running with full field strength, the alternator will have to be removed from the engine and checked as outlined below if the system wiring and battery are good.

BENCH TESTS

1. Remove pulley, fan and spacer from shaft. Remove brushes. Remove through bolts holding unit together and remove drive end housing and rotor assembly.
2. To test the rotor without removing it from end housing, measure the resistance of the coil by placing the prods of an ohmmeter on the slip rings. If the meter reads from 3.8 to 4.2 ohms the rotor is good. If very little resistance is read, it would indicate a possible shorted coil circuit. Check for loose or broken wire at the slip rings. If no resistance is read, the coil is open. Should no loose or broken wires be detected at the slip rings, the short or open is within the rotor coils and the rotor is beyond repair.
3. Upon removal of the brushes it is found that the brush springs are collapsed, the rotor has a shorted coil and the rotor should be replaced.
4. Check the slip ring brushes or springs. If the brushes or springs are cracked, broken or burned, they should be replaced. Brushes worn to a length less than $\frac{3}{16}$" are too short and must be replaced.
5. If the rotor checks good, the stator and rectifier sections should be tested. This can be accomplished without removing the stator and rectifier sections from the slip ring end housing.

Rectifier Tests On Units Having An "N" Terminal

Place the positive prod of an ohmmeter on the "N" terminal at the slip ring end housing and the negative prod on the "B" terminal. With the prods in this position, the meter will read approximately 4 to 5 ohms and indicate that this is the positive section rectifiers. With the prods reversed, the meter needle will read infinity (excessive resistance) which will indicate that the rectifiers are good. Color coding on bottom of rectifiers is red.

Place the negative prod of the ohmmeter on the "N" terminal and the positive prod on the "GRD" terminal. The ohmmeter will read approximately 4 to 5 ohms and indicate that this is the negative ground section. Reversing the position of the prods will make the meter read infinity. Color coding on bottom of rectifiers is black.

Rectifier Test On Units Without "N" Terminal

Since there is no "N" (neutral) terminal, it will be necessary to make the tests at the rectifier sections.

Place the negative prod of an ohmmeter on any one of the three lead connections between the stator and rectifier cells. Place the positive prod on the heat sink of the insulated section of rectifiers. The meter should read 4 to 5 ohms. Reverse the prod position and the meter should read infinity and indicate that this is the positive or grounded section of rectifiers.

Place the positive prod on any one of the lead connections between stator and rectifier cells and the negative prod on the opposite heat sink. The meter should read 4 to 5 ohms. Reverse the prod positions and the meter will read infinity indicating that this is the negative rectifier section.

When making the above tests, if the meter readings do not fall in the category mentioned above, one or more of the rectifiers in the section are not operating properly and the section should be replaced. When replacing rectifiers, be certain that the correct section is grounded.

Alternate Rectifier Test

If an ohmmeter is not available a #57 bulb may be used to test the silicon rectifiers. This test is basically the same except that the bulb and battery replaces the ohmmeter.

If the bulb lights in one direction only the rectifiers are good.

If the bulb lights in both directions one or more of the cells in the section are shorted and the section found bad should be replaced.

If the bulb does not light in either direction one or more of the cells in the section are open and the section should be replaced.

Rectifier Section, Replace

To replace one or both rectifier sections, remove the nuts, etc. from the "B" terminal and the bolt holding the rectifier sections opposite the "B" terminal, and in the case of negative ground units, the "N" terminal. Remove stator and rectifier section from slip ring housing and unsolder the stator leads from the rectifier section or sections to be replaced.

When resoldering the rectifier sections to the stator leads, care must be exercised to apply only enough heat to insure a good connection. Overheating may damage the rectifier cells.

Stator Ground Test

To ground test the stator it will be necessary to unsolder the AC stator leads from the rectifiers. Check each stator phase for grounds to the stator core. A 110 volt test lamp is used for this test. No circuit should be present.

Stator Winding Continuity Test

With the test lamp check the continuity of each of the three stator phases. Each phase should show a closed circuit.

DISASSEMBLY & INSPECTION

After the foregoing tests are completed and the part or parts found inoperative are replaced, the following inspection and cleaning of parts should be done.

Rotor

If the rotor has seen considerable service and the slip rings appear to be worn, they should be replaced. Check shaft threads. Press rotor from housing using an arbor press.

To disassemble rotor, unsolder both field coil leads from the slip rings and, using a small puller, carefully pull off the rings. In some cases it will be impossible to save the old slip rings due to the tight fit on the shaft.

To clean the rotor it may be washed with a brush dipped in a cleaning solvent or paint thinner. Rinse with another brush dipped in unleaded gasoline or kerosene and then wipe with a dry cloth or blow dry with compressed air. *Do not immerse complete rotor in the cleaning fluid.*

Stator

After visual inspection finds the stator free of broken or cracked insulation or other damage which would cause failure, the stator can be cleaned in the same manner described for the rotor.

Brushes, Bearings, Etc.

Replace worn or broken brushes, insulation washers, etc. and inspect all tapped holes for good threads. It is recommended that bearings be replaced at time of overhaul.

Remove bearing retainer screws and bearing retainer from drive end housing. Tap or press out bearing. With bearing removed, housing can be immersed in cleaning solvent or paint thinner for cleaning.

The slip ring end housing bearing needs no special tool for removal or replacement. It may be tapped or pressed out. However, a piece of fiber or similar material should be placed over the new bearing when installing to prevent damage.

REASSEMBLY

The alternator should be assembled in the reverse order of disassembly. Care should be exercised not to damage the housing pilots and stator windings. When completely assembled, spin the rotor by hand for free rotation check.

Reinstall the alternator on the vehicle and run it "full field" as outlined under Alternator System Check.

REGULATOR, ADJUST

Load Relay

To check the load relay, connect leads from a 12 volt battery to the ground and ignition terminals on the regulator, with a variable resistor in series with one lead. Connect a voltmeter across the "IGN" and "GRD" terminals.

Start with all the resistance cut in and then gradually decrease it to allow the voltmeter reading to rise. The load relay should close at .58 to 6.2 volts.

To raise the closing voltage, increase the spring tension by bending the lower arm of the spring bracket. To lower the closing voltage decrease the spring tension.

Voltage Regulator

To check the voltage regulator remove the cover. Connect one voltmeter lead to the regulator "BAT" terminal and the other lead to the regulator or alternator ground. Then connect a pair of earphones of not less than 1,000 ohms resistance to the "FLD" and "GEN" regulator terminals to hear the operation of the regulator contacts. *After each of the three steps in the test, open the ignition switch to bring the alternator speed to zero.*

1. Raise alternator speed slowly and listen for the vibration indicating the start of regulation on the upper contacts. This should start within the range of 13.9 and 14.3 volts. To increase the voltage, bend the lower

Prestolite Alternators

TESTING SYSTEM IN VEHICLE

Charging Circuit Resistance Test

1. Make connections as shown in Fig. P1.
2. Adjust engine speed and electrical load to obtain amperes in the charging circuit. The voltage drop in this circuit should not exceed .2 volt. If more, locate and correct cause of high resistance before proceeding with tests.
3. With the same operating conditions as in Step 2, connect voltmeter leads from ground battery terminal to alternator frame, and from alternator to regulator base. In neither case should the voltage reading exceed .04 volt. If more, locate and correct cause of high resistance ground connections.

Alternator Output Test

1. Make test connections as shown in Fig. P2. *Be sure rheostat is "Off" before connecting leads.*
2. Connect a tachometer, start engine and adjust its speed to 1750 rpm. Adjust rheostat to obtain 14.2 volts and observe ammeter reading. It should be as specified for the alternator being serviced.
3. If the alternator fails to reach rated output, it should be removed from the vehicle for repairs. A slightly low ammeter reading may indicate an open rectifier while a considerably lower reading may indicate a shorted rectifier.
4. If the output is only slightly low, a

Fig. P1 Meter connections for testing voltage drop in charging circuit

Fig. P2 Meter connections for testing alternator output

temperature check may be made to determine whether a rectifier is open. With the alternator operating as for the output test, place a bulb-type thermometer (250° scale) on the base of each rectifier heat sink for the rectifier bank being checked.

5. The rectifier temperature will normally be several degrees higher than the heat sink temperature. If the rectifier is open its temperature will be the same as that of the heat sink in which it is located.
6. If the rectifier is shorted the temperature of the entire heat sink in which it is located will be abnormally high.

Voltage Regulator Test

The first part of this test checks the operating voltage of the regulator when operating on the upper contact. Make test connections as shown in Fig. P3. *Be sure the ignition switch is off when connecting the field lead. Grounding of the field circuit while the ignition switch is on will damage the regulator.*

1. To test votage regulator setting, start engine and adjust its speed to 750 rpm. Turn on lights and accessories to obtain a 10-ampere charge rate. Operate the system at this speed and load for 15 minutes to normalize the temperature. (This regulator is temperature compensated.)
2. Cycle the system by stopping and restarting the engine; then note the voltmeter reading. If seriously out of adjustment a rough setting may be made. The final setting is not made until the "spread" between operation on the upper contact and operation on the lower contact is established. This value is determined in the next part of the test which checks voltage when the regulator is operating on the lower contact.
3. Test connections remain as for the previous part of the test. Increase engine speed to 1500 rpm and turn off all lights and accessories. Voltage should increase and amperage should decrease. The "spread" in voltage between this reading and the reading noted in the first part of the test should be from .1 to .3 volt.
4. If the "spread" is greater or less than specified, remove the regulator cover and adjust by loosening the stationary contact support screw and moving the support up or down. Raising the support will increase voltage "spread", and vice-versa.
5. Replace the cover and reduce engine speed to 750 rpm and repeat the first part of the test with the regulator operating on the upper contact. If the voltage setting is not within specifications, remove the cover and adjust by bending the lower spring hanger. Replace the cover and cycle after each trial adjustment to obtain accurate readings.

Indicator Light Relay Test

1. Make meter connections as shown in Fig. P4. *If the vehicle indicator light cannot be seen while making this test, connect a 12-volt test lamp, using a No. 57 bulb between the "L" and "B" terminals of the regulator.*
2. Turn the rheostat to the "resistance in" position and operate the engine at approximately 800 rpm. Slowly cut out resistance and observe the ammeter reading when the vehicle indicator or test light goes out. It should be 4 to 7 amperes.
3. To adjust relay contact opening amperage, remove the cover and

Fig. P3 Meter connections for testing voltage regulator

Fig. P4 Meter connections for testing indicator light relay operation

Fig. P5 Exploded view of an Auto-Lite & Prestolite alternator

bend the lower armature spring hanger up or down. Increasing the spring tension raises the setting, and vice versa. Replace the cover and recheck.

BENCH TESTS

If the voltage regulator is unstable or cannot be adjusted to specifications in the above test, remove the regulator from the vehicle for further tests and adjustments.

Voltage Regulator Contact Gap

Contact gap is checked by placing a .010″ gauge between the lower movable contact and the lower stationary contact. Adjust by bending the upper stationary contact up or down. Be sure that proper contact alignment is maintained.

Voltage Regulator Air Gap

To check the voltage regulator armature air gap, connect a No. 57 bulb in series with a 12-volt battery between the regulator field terminal and base.

Place a .034″ round wire gauge between the armature and core on the side of the brass stop rivet nearest the center of the core head.

The lower movable contact should barely touch the lower stationary contact when the armature is pressed down against the gauge and the lamp should light. With a .038″ gauge between the armature and core the light should go out.

To adjust to the above specifications, loosen the stationary bracket attaching screw and move the bracket up or down. *This is a preliminary adjustment only as the air gap may be changed when voltage "spread" is established as outlined previously.*

Servicing Regulator Contacts

If the contacts are rough or oxidized, they may be cleaned with an American Swiss No. 6 equalling cut file. After filing, the contacts should be cleaned with a strip of linen tape saturated with a few drops of lighter fluid and drawn between the contacts. Then repeat with a dry strip of tape to remove fluid.

Fig. P6 Removing drive end head and bearing

Fig. P7 Removing roller bearing from slip ring end head

ALTERNATOR REPAIRS

When repairing an alternator, Fig. P5, complete disassembly may not be required. In some cases it will be necessary only to perform those operations that are required to repair or replace the defective part. However, the following material covers the complete overhaul procedure.

Disassembly

1. Remove through bolts and tap lightly on end heads to separate them from stator.
2. Remove drive end head and rotor.
3. Remove nuts, etc., from rectifier bracket studs. Separate slip ring end from stator.
4. Both brushes are located in slip ring end housing and should be replaced if worn to $\frac{5}{16}$″ or less. Remove brushes, being careful that the brush springs are not lost when brushes are removed from holders.
5. Remove pulley and fan.
6. Remove drive end head and bearing, Fig. P6.
7. Remove three screws from retainer plate and press bearing out of drive end head, using tool shown in Fig. P13.
8. Remove roller bearing from slip ring end head, Fig. P7.
9. If rectifiers must be removed, cut rectifier wire as near to crimped sleeve as possible. Then remove rectifiers, Fig. P8.

Inspection

1. When disassembled, all parts should be wiped clean and inspected for wear, distortion or signs of overheating or mechanical interference.
2. Stator windings and leads should be examined for insulation failures or defects. A shorted phase winding or rectifier will normally be evidenced by discoloration.

Fig. P8 Removing rectfiers from heat sink

Fig. P9 Testing rotor for grounds

Fig. P10 Meter connections for testing rotor field current draw

3. The stator can be checked for shorted windings with an internal-external growler. The test is made with the stator leads disconnected from rectifiers.
4. The stator can be checked for grounded windings with a 110-volt test lamp and test probes. *Do not make this test with rectifiers connected to stator leads.*
5. Test rectifiers as described below.
6. The rotor should be tested for grounds and for shorted turns in the winding. The ground test is made with the test probes connected in series with a 110-volt test lamp as shown in Fig. P9. If bulb lights, rotor winding is grounded. To test for shorted turns, check rotor field current draw as shown in Fig. P10. Using the rheostat, adjust voltage to 10 volts and read field current draw on ammeter. Reading should be 2.34 to 2.42 at room temperature (70°F). Excessive current draw indicates shorted turns in field winding.

Assembly

1. Press rectifiers in heat sink, Fig. P11. *Rectfiers are identified by red markings on positive and black markings on negative.* Strip the insulation back about ¼″ on stator leads and reconnect them to rectifiers. The connector sleeves should be crimped on rectifier leads. *Do not solder these connections as the excessive heat may damage rectifiers.*
2. Install roller bearing, Fig. P12. Enclosed end of bearing should be flush with outer surface of end frame when installed.
3. Install felt retainer and crinkle washer and press bearing into drive end frame. Use a flat block 2″ square so that pressure is exerted on outer race. Replace retainer plate and gasket on end frame. Make sure snap ring and retainer are in place on rotor shaft and press end frame on, Fig. P13. Press bearing down against snap ring retainer.
4. Replace spacer on shaft and install Woodruff key, fan and pulley.
5. Install brush springs and brushes. Eyelet on ground brush lead is fastened to end frame with a screw. The blade terminal on the insulated brush lead is pushed into the slot in field terminal insulator bushing. A tab on blade terminal snaps into insulator bushing. If damaged, this bushing may be replaced.
6. To spread brushes so they will clear slip rings when end head is installed, a wire slip can be made and used as shown in Fig. P14. This clip can be fashioned from a coat hanger or ⅛″ welding rod cut and bent to the dimensions shown. File a "V" groove in ends of wire clip so that it will contact brush leads when inserted through holes in end head.
7. Install negative rectifier heat sink in slip ring end head and install lockwashers and nuts. Install insulator bushings on positive heat sink studs and install heat sink in end head. Install outer insulator bushings, washers and nuts.
8. Manually press stator in position on slip ring end head and install assembled drive end head and rotor. Make sure that through bolt holes line up on the two end heads. Install and tighten through bolts.
9. Remove brush spreader clip and make sure brush leads do not drag on rotor and that rotor turns freely when rotated by hand. Test alternator when assembled.

Fig. P11 Installing rectifiers in heat sink

Fig. P12 Installing roller bearing

Fig. P13 Installing drive end head and bearing

TESTING RECTIFIERS

There are two methods of testing diode rectifiers. One method requires the use of Tool C-3829, shown in Figs. P15, P16. The other is to make the tests with a No. 57 bulb test lamp. The advantage of the former over the latter is that it is not necessary to perform the time consuming job of separating the soldered leads. (The instrument is available through the Miller Mfg. Co., Alliance, Ohio.)

Fig. P14 Brush spreader clip. Right view shows clip installed

Fig. P15 Testing positive case rectifiers (Chrysler and Auto-Lite)

Fig. P16 Testing negative case rectifiers (Chrysler and Auto-Lite)

If the current output test indicates that the alternator is not operating within specifications, remove the alternator from the vehicle and proceed as follows:

1. Perform a field coil draw test to provide an indication of the alternator field.
2. Open the alternator by first removing the brushes and then the alternator through bolts. Separate the drive end housing from rectifier end housing.
3. Inspect alternator components, paying special attention to the condition of the slip rings for indications of oil and for being burnt or worn. Check the brushes for evidences of sticking in the holder or housing.
4. Inspect the bearing surfaces of the rotor shaft at the rectifier end and the bearing. Make sure rectifier leads are in good condition, especially at the connections. The insulation should not be worn or broken.

Testing Rectifiers With Tool C-3829

Positive Case Rectifiers In Heat Sink, Fig. P15—Place alternator on an insulated pad and plug instrument (C-3829) into a 110-volt supply. Connect clip of instrument to "Bat" terminal and touch test prod to bare metal of each of positive case rectifier lead wires in heat sink at rectifiers.

Always contact connection nearest rectifiers. Do not break sealing on rectifier lead wire or on top of rectifier. Sealing material is used for corrosion protection.

The meter reading for each of the rectifiers should be the same. The reading on the meter will indicate two amperes or more for good rectifiers.

Where two of the rectifiers are good and one is shorted, the reading taken at the good rectifiers will be low and zero at the shorted one. Cut the lead at the bad rectifier and the reading at the two good rectifiers will be normal.

Where one of the rectifiers is open, it will read low (one ampere or less) and the two good rectifiers will show normal.

Negative Case Rectifiers In End Housing, Fig. P16—Connect the clip of the instrument to the end housing. Touch test prod to the bare wire of the rectifier leads at the rectifiers.

The test indications are the same as the negative rectifiers. However, the meter will read at the opposite end of the scale.

Testing Rectifiers With Test Lamp

1. With alternator disassembled and rectifier leads disconnected, proceed as follows:
2. With a No. 57 test lamp, connect one side of the lamp to the positive battery post and the other side of the lamp to a test probe. Connect another test probe to the negative battery post.
3. Touch the outer case of the rectifier with one probe and the other probe to the wire in the center of the rectifier.
4. Reverse the probes.
5. If the test lamp lights in one direction the rectifier is good. If the lamp lights in both directions the rectifier is shorted. If the lamp does not light in either direction the rectifier is open.

STARTER TROUBLE CHECK-OUT

WHEN TROUBLE develops in the starting motor circuit, and the starter cranks the engine slowly or not at all, several preliminary checks can be made to determine whether the trouble lies in the battery, in the starter, in the wiring between them, or elsewhere. Many conditions besides defects in the starter itself can result in poor cranking performance.

To make a quick check of the starter system, turn on the headlights. They should burn with normal brilliance. If they do not, the battery may be run down and it should be checked with a hydrometer.

If the battery is in a charged condition so that the lights burn brightly, operate the starting motor. Any one of three things will happen to the lights: (1) They will go out, (2) dim considerably or (3) stay bright without any cranking action taking place.

If Lights Go Out

If the lights go out as the starter switch is closed, it indicates that there is a poor connection between the battery and starting motor. This poor connection will most often be found at the battery terminals. Correction is made by removing the cable clamps from the terminals, cleaning the terminals and clamps, replacing the clamps and tightening them securely. A coating of corrosion inhibitor (vaseline will do) may be applied to the clamps and terminals to retard the formation of corrosion.

If Lights Dim

If the lights dim considerably as the starter switch is closed and the starter operates slowly or not at all, the battery may be run down, or there may be some mechanical condition in the engine or starting motor that is throwing a heavy burden on the starting motor. This imposes a high discharge rate on the battery which causes noticeable dimming of the lights.

Check the battery with a hyrdometer. If it is charged, the trouble probably lies in either the engine or starting motor itself. In the engine, tight bearings or pistons or heavy oil place an added burden on the starting motor. Low temperatures also hamper starting motor performance since it thickens engine oil and makes the engine considerably harder to crank and start. Also, a battery is less efficient at low temperatures.

In the starting motor, a bent armature, loose pole shoe screws or worn bearings, any of which may allow the armature to drag, will reduce cranking performance and increase current draw.

In addition, more serious internal damage is sometimes found. Thrown armature windings or commutator bars, which sometimes occur on over-running clutch drive starting motors, are usually caused by excessive over-running after starting. This is the result of such conditions as the driver keeping the starting switch closed too long after the engine has started, the driver opening the throttle too wide in starting, or, improper carburetor fast idle adjustment. Any of these subject the over-running clutch to extra strain so it tends to seize, spinning the armature at high speed with resulting armature damage.

Another cause may be engine backfire during cranking which may result, among other things, from ignition timing being too far advanced.

To avoid such failures, the driver should pause a few seconds after a false start to make sure the engine has come completely to rest before another start is attempted. In addition, the ignition timing should be reset if engine backfiring has caused the trouble.

Lights Stay Bright, No Cranking Action

This condition indicates an open circuit at some point, either in the starter itself, the starter switch or control circuit. The solenoid control circuit can be eliminated momentarily by placing a heavy jumper lead across the solenoid main terminals to see if the starter will operate. This connects the starter directly to the battery and, if it operates, it indicates that the control circuit is not functioning normally. The wiring and control units must be checked to locate the trouble, Fig. 1.

If the starter does not operate with the jumper attached, it will probably have to be removed from the engine so it can be examined in detail.

Checking Circuit With Voltmeter

Excessive resistance in the circuit between the battery and starter will reduce cranking performance. The resistance can be checked by using a voltmeter to measure voltage drop in the circuits while the starter is operated. There are three checks to be made:

1. Voltage drop between car frame and grounded battery terminal post (not cable clamp), Fig. 2.
2. Voltage drop between car frame and starting motor field frame, Fig. 3.
3. Voltage drop between insulated battery terminal post and starting motor terminal stud (or the battery terminal stud of the solenoid), Fig. 4.

Each of these should show no more than one-tenth (0.1) volt drop when the starting motor is cranking for more than 30 seconds at a time to avoid overheating it.

Fig. 2 Checking voltage drop between vehicle frame and grounded battery terminal post

Fig. 3 Checking voltage drop between vehicle frame and starter field frame

Fig. 4 Checking voltage drop between ungrounded battery terminal post and battery terminal on solenoid

Fig. 5 A simple tester for use in making continuity and ground tests on armature and field windings

Fig. 6 Checking armature for grounds. If lamp lights armature is grounded and should be replaced

If excessive voltage drop is found in any of these circuits, make correction by disconnecting the cables, cleaning the connections carefully, and then reconnecting the cables firmly in place. A coating of vaseline on the battery cables and terminal clamps will retard corrosion.

NOTE—On some cars, extra long battery cables may be required due to the location of the battery and starter. This may result in somewhat higher voltage drop than the above recommended 0.1 volt. The only means of determining the normal voltage drop in such cases is to check several of these vehicles. Then when the voltage drop is well above the normal figure for all cars checked, abnormal resistance will be indicated and correction can be made as already explained.

STARTING MOTOR SERVICE

To obtain full performance data on a starting motor or to determine the cause of abnormal operation, the starting motor should be submitted to a no-load and torque test. These tests are best performed on a starter bench tester with the starter mounted on it.

From a practical standpoint, however, a simple torque test may be made quickly with the starter in the car. Make sure the battery is fully charged and that the starter circuit wires and terminals are in good condition. Then operate the starter to see if the engine turns over normally. If it does not, the torque developed is below standard and the starter should be removed for further checking.

Remove starter from engine and disassemble as outlined in the following text and make the tests as suggested in Figs. 6 through 11.

AUTO-LITE STARTERS

Two types of starters are in general use. Heavy duty engines are equipped with the unit shown in Fig. 12 and light duty engines use the one shown in Fig. 13. In both motors the brush holders are riveted to a separate brush plate and are not serviced separately. Brush replacement is accomplished by removing the bearing end frame and armature.

Disassembling Overrunning Clutch Motor

1. Referring to Fig. 12, remove roll pin from shifting fork and solenoid coupling pin.
2. Remove solenoid.
3. Support solenoid coupling pin and drive out roll pin.
4. Remove solenoid rubber boot, plunger spring and coupling pin.
5. Remove thru bolts and take out commutator and cover, thrust washer and insulators.

Fig. 7 Measuring commutator runout with a dial indicator. Mount shaft in V blocks and rotate commutator. If runout exceeds .003", commutator should be turned in a lathe to make it concentric

Fig. 8 Turning commutator in a lathe. Take light cuts until worn or bad spots are removed. Then remove burrs with No. 00 sandpaper

Fig. 9 Good undercutting should be .002" wider than mica insulation, 1/64" deep and exactly centered so that there are no burrs on the mica

Fig. 10 Checking armature for short circuit. As armature is rotated by hand, steel strip (hacksaw blade) will vibrate if short circuit exists

6. Remove drive end housing, drive fork and armature from field frame.
7. Remove roll pin attaching shifting fork to pinion housing and remove retainer, dust cover and shifting fork.
8. Remove spacer and slide pinion gear toward commutator end of armature; then drive stop collar toward pinion and remove lock ring.
9. Slide starter drive from armature.
10. Remove brush holder ring from field frame (3 screws).
11. Disconnect field lead wire at brush holder ring, disengage the brushes from the holders and carefully slide brush holder ring from field frame.

Disassembling Folo-Thru Drive Motor

1. Refer to Fig. 13, remove thru bolts and tap commutator end frame from field frame.
2. Remove brush holder ring from field frame (3 screws).
3. Disconnect field lead wire at brush holder ring, disengage brushes from holders and carefully slide brush holder ring from field frame.
4. Remove set screw from drive and armature shaft by prying back drive spring to expose screw under spring.
5. Tap drive assembly from armature shaft and remove woodruff key.
6. Slide center bearing plate from armature shaft.

Overrunning Clutch

Place drive unit on shaft and, while holding armature, rotate pinion. The drive pinion should rotate smoothly in one direction (not necessarily easily), but should not rotate in the opposite direction. If drive unit does not function properly or pinion is worn or burred, replace drive unit.

Fig. 11 Testing field coils for grounds. Lamp will light if a ground is present

Folo-Thru Drive

This type of drive, Fig. 14, is serviced only as an assembly. To clean and oil the drive with armature removed, use a screwdriver to pry back the drive spring to expose the attaching set screw. Back

Fig. 12 Auto-Lite four field coil starter with overrunning clutch drive

Fig. 13 Auto-Lite three field coil starter with Folo-Thru drive

out the set screw far enough to clear armature shaft and slide drive off end of armature shaft. Wipe armature shaft clean and dry and re-oil with SAE 10W oil. Rotate pinion and barrel to the fully engaged position and apply clean kerosene with a brush to the screw shaft threads. Wipe dry and apply a light film of SAE 10W oil to the screw shaft threads and a few drops of oil under the spring on the thrust washer.

Assembling Starter

Reassembly procedure is the reverse of disassembly. However, on Folo-Thru drive motors, be sure the starter drive set screw is seated in the armature shaft; be sure the end frames are positioned on dowel pins; and be sure that the slots in the intermediate bearing and commutator end head line up with the indexing pins in the frame before installing and tightening thru bolts.

CHRYSLER DIRECT DRIVE STARTER

This Chrysler built starting motor, Fig. 15, is a four coil assembly with an over-running clutch type drive and a solenoid shift-type switch mounted on the motor. The brush holders are riveted to a separate brush plate and are not serviced individually. Brush replacement can be made by removing the commutator bearing end head.

Fig. 14 Folo-Thru starter drive

Disassembly

1. Remove through bolts and tap commutator end head from field frame.
2. Remove thrust washers from armature shaft.
3. Lift brush holder springs and remove brushes from holders.
4. Remove brush plate.
5. Disconnect field leads at solenoid connector.
6. Unfasten and remove solenoid and boot assembly.
7. Drive out over-running clutch shift fork pivot pin.
8. Remove drive end pinion housing and spacer washer.
9. Note position of shifter fork on starter and remove fork.
10. Slide over-running clutch pinion gear toward commutator end of armature. Drive stop retainer toward clutch pinion gear to expose snap ring and remove snap ring.
11. Slide clutch drive from armature shaft.
12. If necessary to replace the field coils, remove screw that holds ground brushes and raise brushes with the terminal and shunt wire up and away from field frame. Remove pole shoe screws and take out field coils.

Reassembly

1. Lubricate armature shaft and splines with SAE 10W or 30W rust preventive oil.

Fig. 15 Chrysler built direct drive starter

2. Install starter drive, stop collar (retainer), lock ring and spacer washer.
3. Install shifter fork over starter drive spring retainer washer with narrow leg of fork toward commutator. *If fork is not positioned properly, starter gear travel will be restricted, causing a lockup in the clutch mechanism.*
4. Install drive end (pinion) housing on armature shaft, indexing the shift fork with slot in drive end of housing.
5. Install shift fork pivot pin.
6. Install armature with clutch drive, shifter fork and pinion housing. Slide armature into field frame until pinion housing indexes with slot in field frame.
7. Install solenoid and boot assembly and tighten bolts securely.
8. Install ground brushes.
9. Connect field coil leads at solenoid connector.
10. Install brush holder ring, indexing tang of ring in hole of field frame.
11. Position brushes in brush holders. *Be sure field coil lead wires are properly enclosed behind brush holder ring and that they do not interfere with brush operation.*
12. Install thrust washer on commutator end of armature shaft to obtain .010″ minimum end play.
13. Install commutator end head.
14. Install through bolts and tighten securely.

Fig. 16 Clearance between end of pinion and pin stop should be 1/8″ with plunger seated and pinion pushed toward commutator

Adjusting Pinion Clearance

1. Place starter in vise with soft jaws and tighten vise enough to hold starter. *Place a wedge or screwdriver between bottom of solenoid and starter frame to eliminate all deflection in solenoid when making pinion clearance check.*
2. Push in on solenoid plunger link, Fig. 16 (not fork lever) until plunger bottoms.
3. Measure clearance between end of pinion and pin stop with plunger seated and pinion pushed toward commutator end. Clearance should be ⅛″. Adjust by loosening solenoid attaching screws and move solenoid fore and aft as required.
4. Test starter operation for free running and install on engine.

CHRYSLER REDUCTION GEAR STARTER

This reduction gear starting motor, Fig. 17, has an armature-to-engine crankshaft ratio of 45 to 1; a 3½ to 1

Fig. 17 Chrysler built reduction gear starter

reduction gear set is built into the motor assembly. The starter utilizes a solenoid shift. The housing of the solenoid is integral with the starter drive end housing.

Disassembly

1. Place gear housing of starter in a vise with soft jaws. *Use vise as a support fixture only; do not clamp.*
2. Remove through bolts and starter end head assembly.
3. Carefully pull armature up and out of gear housing, and starter frame and field assembly. Remove steel and fiber thrust washer. *The wire of the shunt field coil is soldered to the brush terminal. One pair of brushes are connected to this terminal. The other pair of brushes is attached to the series field coils by means of a terminal screw. Carefully pull the frame and field assembly up just enough to expose the terminal screw and the solder connection of the*

Fig. 18 Removing brush terminal screw

Fig. 19 Unsoldering shunt field coil lead from starter brush terminal

Fig. 20 Remove brush insulator which prevents contact between brush terminal and gear housing. Remove screw attaching brush holder plate to gear housing

shunt field at the brush terminal. Place two wood blocks between starter frame and gear housing, Fig. 18, to facilitate removal of terminal screw and unsoldering of shunt field wire at brush terminal.

4. Support brush terminal by placing a finger behind terminal and remove screw, Fig. 18.
5. Complete the disassembly procedure by referring to Figs. 19 through 33.

Fig. 21 Remove brush holder plate with brushes and solenoid as a unit

Fig. 22 Unsolder solenoid winding from brush terminal

Fig. 23 Remove nut, steel washer and nylon washer from solenoid terminal. Separate brush holder plate from solenoid

Fig. 24 Remove nut, steel washer and nylon washer from starter battery terminal. Remove terminal from holder plate. Then remove solenoid contact assembly

Fig. 25 Remove solenoid coil sleeve

Fig. 26 Remove solenoid return spring (Fig. 21). Then remove solenoid coil retainer washer and retainer from solenoid housing

Fig. 27 Remove dust cover from gear housing

Fig. 28 Release snap ring that positions driven gear on pinion shaft. This ring is under tension and a cloth should be placed over ring to prevent it from springing away after removal

Fig. 29 Release retainer ring at front of pinion shaft. Do not spread ring any greater than the outside diameter of pinion shaft otherwise ring can be damaged

Fig. 30 Push pinion shaft toward rear of housing and remove snap ring and thrust washers

Fig. 31 Lift out clutch and pinion assembly with the two shift fork nylon actuators

Fig. 32 Remove driven gear and friction washer. Then pull shift fork forward and remove solenoid moving core

Fig. 33 Remove shift fork retaining pin and take out shift fork

Reassembly

The shifter fork consists of two spring steel plates assembled with two rivets, Fig. 34. There should be about $\frac{1}{16}$" side movement to insure proper pinion gear engagement. Lubricate between plates sparingly with SAE 10 engine oil.

1. Position shift fork in drive housing and install fork retaining pin, Fig. 33. *One tip of pin should be straight, the other tip should be bent at a 15 degree angle away from housing. Fork and pin should operate freely after bending tip of pin.*
2. Install solenoid moving core and engage shifting fork, Fig. 32.
3. Enter pinion shaft in drive housing and install friction washer and driven gear.
4. Install clutch and pinion assembly, Fig. 31, thrust washer, retaining ring, and thrust washer.
5. Complete installation of pinion shaft, engaging fork with clutch actuators, Fig. 35. *Friction washer must be positioned on shoulder of splines of pinion shaft before driven gear is positioned.*
6. Install driven gear snap ring, Fig. 29. Install pinion shaft retaining ring, making sure ring fits tightly in shaft groove.

Fig. 34 Shifter fork assembly

Fig. 35 Shifter fork and clutch arrangement

Fig. 36 Installing solenoid coil and sleeve

7. Install solenoid coil retainer, Fig. 26, with tangs down. *Space retainer in housing bore so that the four tangs rest on ridge in housing bore and not in the recesses.*
8. Install solenoid retainer washer.
9. Install solenoid return spring, Fig. 21. *Inspect condition of solenoid switch contacting washer. If top of washer is burned from arcing, disassemble switch and reverse washer.*
10. Install solenoid contact into solenoid, Fig. 24. Make sure contact spring is positioned in solenoid contact. *Inspect condition of contacts in brush holder plate. If contacts are badly burned, replace brush holder with brushes and contacts as an assembly.*

Fig. 37 Positioning brushes with Tool Set C-3855

Fig. 38 Installing armature

Fig. 39 Removing brush positioning tools

11. Enter solenoid lead wire through hole in brush holder, Fig. 23, and solenoid stud, insulating washer, flat washer and nut.
12. Solder solenoid lead wire to contact terminal, Fig. 22. Wrap wire securely around terminal and solder with a high temperature solder and resin flux.
13. Carefully enter solenoid coil and coil sleeve into bore of gear housing and position brush plate assembly into gear housing, Fig. 36. Align tongue

Fig. 40 Delco-Remy Standard Duty starter with enclosed shift lever

of ground terminal with notch in brush holder.

14. After brush holder is bottomed in housing, install attaching screw, Fig. 20. Tighten screw and install flat insulating washer and holder in place with friction tape.
15 Position brushes with tools shown in Fig. 37 or equivalent.
16 Position field frame to exact position and resolder field coil lead, Fig. 19.
17. Install brush terminal screw, Fig. 18.
18. Install armature thrust washer on brush holder plate and enter armature into field frame and gear housing, Fig. 38. Carefully engage splines of shaft with reduction gear.
19. Remove brush positioning tools, Fig. 39. Install fiber and steel thrust washers on armature shaft.
20. Position starter end head, install screws and tighten securely.
21. Install gear housing dust cover. *Make sure dimples on cover are securely engaged in holes provided in gear housing.* Test starter for free running and install on engine.

DELCO-REMY STANDARD DUTY ENCLOSED SHIFT LEVER TYPE MOTOR

This type starting motor, Fig. 40, has the solenoid shift lever mechanism and the solenoid plunger enclosed in the drive housing, thus protecting them from exposure to road dirt, icing conditions and splash. They have an extruded field frame and an overrunning clutch type of drive. The overrunning clutch is operated by a solenoid switch mounted to a flange on the drive housing.

Solenoid

The solenoid is attached to the drive end housing by two screws. The angle of the nose of the plunger provides a greater bearing area between the plunger and core tube. A molded push rod, Fig. 41, is assembled in the contact assembly. A shoulder molded on the push rod and a cup that can easily be assembled to the rod and locked into position over two molded bosses holds the contact assembly in place.

To disassemble the cup from the push rod, push in on the metal cup and rotate ¼ turn so the molded bosses on the rod are in line with openings in the cup; then slide the metal cup off the rod.

To assemble the metal cup on the rod, locate the parts on the rod as shown and align the large openings in the cup with the molded bosses on the rod; then push in on the cup and rotate it ¼ turn so the small bosses on the rod fall into the keyways of the cup.

Fig. 41 Solenoid contact assembly

Solenoid Terminals

The terminals of the solenoid are assembled in a molded cover. Some solenoids have an additional small terminal which is identified with the letter "R". To this terminal is attached a small metal finger which makes contact with a disc inside the solenoid when it is energized. On the vehicle, this terminal is connected to the battery side of the ignition coil. The purpose of this is to short out the ignition resistor during cranking and thereby provide high ignition coil output for starting the engine.

Maintenance

Most motors of this type have graphite and oil impregnated bronze bearings which ordinarily require no added lubrication except at time of overhaul when a few drops of light engine oil should be placed on each bearing before reassembly.

Motors provided with hinge cap oilers should have 8-10 drops of light engine oil every 5000 miles, or every 300 hours of operation. Since the motor and brushes cannot be inspected without disassembling the unit, there is no service that can be performed with the unit assembled on the vehicle.

Starting Motor Tests

Free Speed Check — With the circuit connected as shown in Fig. 42, use a tachometer to measure armature revolutions per minute. Failure of the motor to perform to specifications may be due to tight or dry bearings, or high resistance connections.

Pinion Clearance—There is no provision for adjusting pinion clearance on this

Fig. 42 Connections for checking free speed of motor

type motor. When the shift lever mechanism is correctly assembled, the pinion clearance should fall within the limits of .010 to .140". When the clearance is not within these limits, it may indicate excessive wear of the solenoid linkage or shift lever yoke buttons.

Pinion clearance should be checked after the motor has been disassembled and reassembled. To check, make connections as shown in Fig. 43. *Caution: Do not connect the voltage source to the ignition coil terminal "R" of the solenoid. Do not use a 12-volt battery instead of the 6 volts specified as this will cause the motor to operate.* As a further precaution to prevent motoring, connect a heavy jumper lead from the solenoid motor terminal to ground.

After energizing the solenoid with the clutch shifted toward the pinion stop retainer, push the pinion back toward the commutator end as far as possible to take up any slack movement; then check the clearance with a feeler gauge, Fig. 44.

Disassembling Motor

Normally the motor should be disassembled only so far as necessary to repair or replace defective parts.

1. Disconnect field coil connectors from solenoid "motor"' terminal.
2. Remove thru bolts.
3. Remove commutator end frame and field frame assembly.
4. Remove armature assembly from drive housing. On some models it may be necessary to remove solenoid and shift lever assembly from the drive housing before removing the armature assembly. *Important: When solenoid is installed, apply sealing compound between field frame and solenoid flange* (Fig. 45).
5. Remove overrunning clutch from armature shaft as follows:
   a) Slide thrust collar off end of armature shaft, Fig. 46.
   b) Slide a standard ½" pipe coupling or other metal cylinder of suitable size onto shaft so end of coupling or cylinder butts against edge of retainer. Tap end of coupling with hammer, driving retainer toward armature and off snap ring.
   c) Remove snap ring from groove in shaft. If snap ring is too badly distorted during removal, use a new one when reassembling the clutch.
   d) Slide retainer, clutch and assist spring from armature shaft.

Fig. 43 Connections for checking pinion clearance

Reassembling Motor, Fig. 47

1. Lubricate drive end and splines of armature shaft with SAE 10 oil. *If heavier oil is used it may cause failure to mesh at low temperatures.*

Fig. 44 Checking pinion clearance

2. Place "assist" spring on drive end of shaft next to armature, with small end against lamination stack.
3. Slide clutch assembly onto armature shaft with pinion outward.
4. Slide retainer onto shaft with cupped surface facing end of shaft.
5. Stand armature on end on wood surface with commutator down. Position snap ring on upper end of shaft and hold in place with a block of wood. Hit wood block with a hammer forcing snap ring over end of shaft. Slide snap ring into groove, squeezing it to ensure a good fit in groove.
6. Assemble thrust collar on shaft with shoulder next to snap ring.
7. Position retainer and thrust collar next to snap ring. With clutch pressed against assist spring, for clearance next to retainer, use two pairs of pliers at the same time (one pair on either side of shaft) to grip retainer and thrust collar. Then squeeze until snap ring is forced into retainer.
8. Place 4 or 5 drops of SAE 10 oil in drive housing bushing. Make sure thrust collar is in place against snap ring and retainer; then slide armature and clutch assembly into place in drive housing.
9. Attach solenoid and shift lever assembly to drive housing. Be sure lever buttons are located between sides of clutch collar.
10. Position field frame over armature, *applying sealing compound between frame and solenoid flange, Fig. 45.* Position frame against drive housing, using care to prevent damage to brushes.
11. Place 4 or 5 drops of SAE 10 oil in bushing in commutator end frame. Make sure leather brake washer is on armature shaft; then slide commutator end frame onto shaft.
12. Install thru bolts and tighten securely.
13. Reconnect field coil connectors to solenoid "motor" terminal.

Fig. 45 Sealing solenoid housing to frame

Cleaning

The overrunning clutch, armature and fields should not be cleaned in any degreasing tank, or with grease dissolving solvents, since these would dissolve the lubricant in the clutch mechanism and would damage the insulation in the armature and field coils. It is suggested that all parts, except the clutch, be

Fig. 46 View of armature and overrunning clutch

cleaned with oleum spirits and a brush. The clutch can be wiped with a clean cloth.

If the commutator is dirty it may be cleaned wth No. 00 sandpaper; *never use emery cloth for this purpose.*

DELCO-REMY HEAVY DUTY ENCLOSED SHIFT LEVER TYPE MOTOR

In this type motor, Figs. 48 and 49, the nose housing can be rotated to obtain a number of different solenoid positions with respect to the mounting flange, which is a feature that makes these motors adaptable to a wide variety of mounting applications.

Positive lubrication is provided to the bronze bushing located in the commutator end frame, in the lever housing, and in the nose housing by an oil saturated wick that projects through each bushing and contacts the armature shaft. Oil can be added to each wick by removing a pipe plug which is accessible on the outside of the motor.

Available as an optional feature is a waste-filled oil reservoir for each wick which makes available a larger supply of oil thereby extending the time required between lubrication periods. Another optional feature is "O" rings which can be added to resist entry of dirt and moisture into the entire motor assembly.

Many models feature a seal between the shaft and lever housing, and all models have a rubber boot or linkage seal over the solenoid plunger. The seal and the boot, when used together, prevent entry of transmission oil into the motor main frame and solenoid case, allowing the motor to be used on wet clutch applications.

Overrunning Clutches

As shown in Fig. 48 and 49, two kinds of clutches, heavy duty or intermediate duty overunning type, may be used with these motors. The clutches may be either the sprag type or the four-roll type. Both types are moved into mesh with the ring gear by the action of the solenoid. Once engaged, the clutch will not disengage during intermittent engine firing, which prevents damage to pinion and ring gear teeth. The pinion remains engaged until starting is assured and the solenoid circuit is interrupted.

Maintenance

Under normal operating conditions, no maintenance will be required between engine overhaul periods. At time of engine overhaul, motors without oil reservoirs and "O" rings, and "long life" motors incorporating "O" rings and oil reservoirs should be disassembled, inspected, cleaned and tested.

Adjustable Nose Housing

Two methods are employed to attach the nose housing to the lever housing. As shown in Fig. 48, one method attaches the nose housing to the lever housing by six bolts located around the outside of the housing. To relocate the housing, it is only necessary to remove the bolts, rotate the housing to the de-

Fig. 47 Disassembled view of starting motor

Fig. 48 Delco-Remy heavy duty enclosed shift lever type motor with heavy duty clutch

Fig. 49 Delco-Remy heavy duty enclosed shift lever type motor with intermediate duty clutch

Fig. 50 Connections for checking free speed of motor

sired position, reinstall the bolts and torque them to 13-17 ft. lb. during reassembly.

In the second method, Fig. 49, the lever housing and commutator end frame are held to the field frame by thru bolts extending from the commutator end frame to threaded holes in the lever housing. The nose housing is held to the lever housing by internal attaching bolts. With this arrangement, it is necessary to partially disassemble the motor to provide access to the attaching bolts when relocating the nose housing.

To accomplish this, remove the electrical connector and the screws attaching the solenoid assembly to the field frame and then remove the thru bolts from the commutator end frame. Separate the field frame from the remaining assembly, and pull the armature away from the lever housing until the pinion stop rests against the clutch pinion. This will clear the nose housing attaching bolts so they can be removed, permitting relocation of the nose housing. During reassembly, torque the nose housing attaching bolts to 11-15 ft. lb.

Fig. 52 Checking pinion clearance on intermediate duty clutch motor

Starting Motor Tests

Free Speed Test—With the circuit connected as shown in Fig. 50, use a tachometer to measure armature revolutions per minute. Failure of the motor to perform to specifications may be due to tight or dry bearings, or high resistance connections.

Pinion Clearance: There are no provisions for adjusting pinion clearance on motors using the intermediate duty clutch. However, this should be checked after reassembly of motor to make sure the clearance is within specifications. To check the pinion clearance, make connections as shown in Fig. 51. After energizing the solenoid with the clutch shifted toward the pinion stop retainer, push the pinion back toward the commutator end as far as possible to take up any slack movement, then check the clearance between pinion and pinion stop retainer with a feeler gauge, Fig. 52, If clearance is not within specified limits, check the solenoid linkage and shift lever yoke buttons for excessive wear.

The pinion clearance for motors using the heavy duty clutch is checked in the same manner as for intermediate duty clutches. The clearance for these motors, however, is measured as indicated in Fig. 53. The clearance is adjustable and is accomplished by removing the plug on the lever housing and turning the nut on the plunger rod inside the housing. Turn the nut clockwise to decrease clearance, and vice versa.

Disassembling Motor

Note the relative position of the solenoid, lever housing and nose housing so the motor can be reassembled in the same manner.

Intermediate Duty Clutch Motor—

1. Disconnect field coil connector from solenoid motor terminal, and remove solenoid mounting screws.
2. Remove thru bolts.
3. Remove commutator end frame from field frame and field frame from lever housing.
4. Remove nose housing attaching bolts and separate nose housing from lever housing.
5. Slide a ½" pipe coupling or other metal cylinder of suitable size onto shaft so end of coupling or cylinder butts against edge of retainer. Tap end of coupling with a hammer, driving retainer toward armature and off snap ring.
6. Remove snap ring from groove in shaft, using pliers or other suitable tool. If snap ring is too badly distorted during removal, use a new one when reassembling clutch.
7. Remove armature and clutch from lever housing.
8. Separate solenoid from lever housing.

Heavy Duty Clutch Motor—

1. Disconnect field coil connector from solenoid motor terminal and lead from solenoid ground terminal.
2. On motors having brush inspection plates, remove plates and then brush lead screws. This will disconnect the field leads from the brush holders.

Fig. 51 Connections for checking pinion clearance

3. Remove attaching bolts and separate commutator end frame from field frame.
4. Separate nose housing and field frame from lever housing by removing attaching bolts.
5. Remove armature and clutch assembly from lever housing.
6. Separate solenoid from lever housing by pulling apart.

Cleaning

Follow cleaning instructions outlined for standard duty motors.

Reassembling Motor

The reassembly procedure for each type of motor is the reverse of disassembly. On motors using a snap ring and retainer on the shaft as a pinion stop, the ring and retainer can be assembled as follows:

With the retainer placed over the shaft with the cupped surface facing the end of the shaft, force the ring over the shaft with a light hammer blow and then slide the ring down into the groove. To force the retainer over the snap ring, place a suitable washer over the shaft and squeeze with pliers. Remove the washer, Fig. 54.

To reassemble the end frame having eight brushes onto the field frame, pull

Fig. 53 Checking pinion clearance on heavy duty clutch motor

Fig. 54 Forcing retainer over snap ring

Fig. 56 Delco-Remy sprag clutch type motor

Fig. 55 Assembling end frame with eight brushes to field frame

the armature out of the field frame just far enough to permit the brushes to be placed over the commutator, Fig. 55. Then push the commutator end frame and the armature back against the field frame.

Lubrication

All wicks and reservoirs should be saturated with SAE 10 oil, and the splines underneath the clutch should be lubricated with a light coat of SAE 10 oil. *Heavier oil may cause failure to mesh at low temperatures.*

DELCO-REMY MOTOR WITH SPRAG CLUTCH DRIVE

The sprag type overrunning clutch, Fig. 56 and 57, has a high torque capacity made possible by dividing the load among many elements called sprags. These sprags are small billets of steel with the upper and lower surfaces rounded so the diagonals across the sprag are of unequal length. When the sprags are rotated so the longer diagonal approaches the vertical, a wedging action occurs, locking the inner race to the outer race. A contracting garter spring, placed around the sprag assembly, holds the sprags in the locked position with the sprags contacting the races so torque can be transmitted without delay when the armature starts rotating. Friction between the sprags and the inner and outer races tends to rotate the sprags in the locking position so that the locking action is increased with load.

When the engine begins to operate, it attempts to drive the starting motor armature faster than the armature rotates under its own power. This causes the pinion assembly to rotate with respect to the armature, and turns the sprags in the opposite direction so they become unlocked, allowing them to slide freely between the inner and outer races of the clutch. Now the pinion assembly can overrun (run faster than) the armature. This protects the armature from

Fig. 57 View of heavy duty sprag clutch

rotating at high speeds during the brief period that the circuit is being broken in the solenoid which will release the clutch. There are two types of sprag clutch, Figs, 58 and 59.

Pinion Clearance

On overrunning clutch motors, including the sprag type, the clearance between the pinion and pinion stop or housing should be checked with the pinion in the cranking position after the motor has been disassembled and reassembled.

Fig. 58 Disassembled view of intermediate duty sprag clutch drive

Fig. 59 Disassembled view of heavy duty sprag clutch drive

Fig. 60 Checking intermediate duty sprag clutch pinion clearance

Fig. 62 Lubricating clutch sprags

To check the pinion clearance on the solenoid type motor, connect a voltage source (about one-half rated voltage so armature does not rotate) between terminals of the solenoid winding. This will shift the clutch pinion into cranking position. As a further precaution to prevent motoring, connect a heavy jumper lead from the solenoid motor terminal to ground. After energizing the solenoid and with the clutch shifted into cranking position, push the pinion back toward the commutator end to take up any slack movement. Then check the clearance as shown in Figs. 60 and 61. If the shift lever is manually controlled, the clutch can be shifted into cranking position by hand to check pinion clearance.

If the specified clearances are not obtained, it may indicate excessive wear of solenoid linkage or shift lever yoke buttons.

Intermediate Duty Sprag Clutch

1. Remove lock wire and collar from sleeve, Fig. 58.

Fig. 61 Checking heavy duty sprag clutch pinion clearance

2. Remove jump spring, spring stop washer and second lock wire.
3. Remove retainer ring and large washers. Do not remove sleeve or sprags from shell.
4. Lubricate sprags, Fig. 62, and saturate the felt washer with SAE 5W20 oil. *Heavier oil must not be used.*
5. Reassemble washers and retaining ring.
6. Assemble lock wire in groove next to sprags; then assemble stop washer.
7. Assemble jump spring, collar and other lock wire.
8. Lubricate armature shaft with a few drops of SAE 10 oil before sprag clutch is reinstalled.

Heavy Duty Sprag Clutch

1. Remove cupped pinion stop and split washer, Fig. 62. In removing cupped pinion stop, it will probably be damaged to the extent that a new one will be required on reassembly.
2. Remove pinion, spring and retainer cups.
3. Remove retainer ring and washers. *Do not remove collar sleeve and shell, or sprags from shell.*
4. Lubricate sprags and saturate felt washer with SAE 5W20 oil — no heavier.
5. Reassemble washers and retainer ring.
6. Lubricate spiral spline on collar sleeve and shell with SAE 10 oil.
7. Assemble retainer cups and spring.
8. Assemble pinion with collar side toward spring, Fig. 62.
9. Install new cupped pinion stop and split washer as shown. Stake cupped pinion stop in about 10 places with a round-nosed tool.

Removing Intermediate Duty Clutch

Removal of the clutch from the armature is accomplished in the same manner as outlined for the intermediate duty clutch on Heavy Duty Motors.

FORD STARTER WITH INTEGRAL POSITIVE ENGAGEMENT DRIVE

This type starting motor, Fig. 63, is a four pole, series parallel unit with a positive engagement drive built into the starter. The drive mechanism is engaged with the flywheel by lever action before the motor is energized.

When the ignition switch is turned on to the start position, the starter relay is energized and supplies current to the motor. The current flows through one field coil and a set of contact points to ground. The magnetic field given off by the field coil pulls the movable pole, which is part of the lever, downward to its seat. When the pole is pulled down, the lever moves the drive assembly into the engine flywheel, Fig. 64.

When the movable pole is seated, it functions as a normal field pole and opens the contact points. With the points open, current flows through the starter field coils, energizing the starter. At the same time, current also flows through a holding coil to hold the movable pole in its seated position.

When the ignition switch is released from the start position, the starter relay opens the circuit to the starting motor. This allows the return spring to force the lever back, disengaging the drive from the flywheel and returning the movable pole to its normal position, Fig. 65.

Disassembly

It may not be necessary to disassemble the starter completely to accomplish repair or replacement of certain parts. Thus, before disassembling the motor, remove the cover band and starter drive actuating lever cover. Examine brushes to make sure they are free in their holders. Replace brushes if defective or worn beyond their useful limit. Check the tension of each brush spring with a pull scale. Spring tension should not be less than 45 ounces. If disassembly is necessary, proceed as follows:

1. Remove cover band and starter drive actuating lever cover.
2. Remove through bolts, starter drive gear housing, drive gear retaining clip cup and starter drive actuating lever return spring.
3. Remove pivot pin retaining starter gear actuating lever and remove lever and armature.
4. Remove and discard spring clip retaining starter drive gear to end of armature shaft, and remove starter drive gear.
5. Remove commutator brushes from brush holders and remove brush end plate.
6. Remove two screws retaining ground brushes to frame, Fig. 66.
7. On the field coil that operates the drive actuating lever, bend tab up on field retainer and remove retainer.
8. Remove field coil retainer screws, Fig. 67. Unsolder field coil leads from terminal screw, and remove pole shoes and coils from frame.
9. Remove starter terminal nut and related parts. Remove any excess solder from terminal slot.

Reassembly

1. Install starter terminal, insulator, washers and retaining nut in frame, Fig. 66. Be sure to position slot in screw perpendicular to frame end surface.
2. Install field coils and pole pieces. As pole shoe screws are tightened, strike frame several sharp blows with a soft-faced hammer to seat and align pole shoes, then stake the screws.
3. Install solenoid coil retainer and bend tabs to retain tabs to frame.
4. Solder field coils and solenoid wire to starter terminal, using rosin core solder.
5. Check for continuity and grounds in the assembled coils.
6. Position solenoid coil ground terminal over ground screw hole nearest starter terminal.
7. Position ground brushes to starter frame and install retaining screws, Fig. 66.
8. Position starter brush end plate to frame with end plate boss in frame slot.
9. Install drive gear to armature shaft and install a new retaining spring clip.
10. Position fiber thrust washer on commutator end of armature shaft and install armature in frame.
11. Install starter drive actuating lever to frame and starter drive, and install pivot pin.
12. Position actuating lever return spring and drive gear housing to frame and install through bolts. Do not pinch brush leads between brush plate and frame.
13. Install brushes in holders, being sure to center brush springs on brushes.
14. Position drive gear actuating lever cover on starter and install brush cover band.
15. Check starter for free running and install on engine.

Fig. 63 Ford starter with an integral positive engagement drive

Fig. 64 Starter drive engaged

Fig. 65 Starter drive disengaged

Fig. 67 Removing field coil pole shoe screws

Fig. 68 Ford starter used with Folo-Thru drive

Fig. 70 Overrunning clutch drive. When assembling make sure curved sides of yoke shoes are toward gear end of clutch. Reversed yoke shoes can cause improper meshing of pinion

FORD STARTER WITH FOLO-THRU DRIVE

Disassembly

1. Remove starter drive, through bolts and rear end plate, Fig. 68. *Be sure to remove all burrs from shaft to prevent scoring rear end plate bushing.*
2. Remove armature, two thrust washers and cover band.
3. Remove brushes from their holders, and remove brush end plate.
4. Unscrew ground brush screws and remove brushes.
5. Remove pole shoe screws (see Fig. 67). Unsolder field coil leads from terminal screw and remove pole shoes and field coils.
6. Remove starter terminal, Remove any excess solder from terminal slot.

Reassembly

1. Install terminal screw with insulator washers and terminal nut. Be sure to position slot in screw parallel to frame end surface.
2. Install field coils. Use rosin core solder and be sure to position shunt coil ground lead under ground brush terminal farthest from starter terminal, Fig. 69. The other shunt coil lead is soldered to the series field coil lead farthest from starter terminal.
3. Install screws that connect ground brushes to starter frame.
4. Install brush end plate, making sure that brush plate boss is located in slot in starter frame. Do not pinch brush leads between frame and end plate.
5. Place thrust washer on each end of shaft, slide armature in place, and install rear end plate with dowel located in starter frame slot.
6. Install through bolts.
7. Install brushes in their holders, being sure to center brush springs on brushes.
8. Install cover band and starter drive. Check starter for free running.

Fig. 69 Field coil assembly

STARTER DRIVE SERVICE

Starter drives fall into one or the other of two basic groups, the type that uses the principle of the over-running clutch, 70 and 72, and the Bendix, which uses the spinning nut principle, Figs. 71 and 73.

Starter drive troubles are easy to diagnose and they usually cannot be confused with ordinary starter difficulties. If the starter does not turn over at all or if it drags, look for trouble in the starter or electrical supply system. Concentrate on the starter drive or ring gear if the starter is noisy, if it turns but does not engage the engine, or if the starter won't disengage after the engine is started. After the starter is removed, the trouble can usually be located with a quick inspection.

Worn or chipped ring gear or starter pinion are the usual causes of noisy operation. Before replacing either or both of these parts, try to find out what caused the damage. With the Bendix type drive, incomplete engagement of the pinion with the ring gear is a common cause of tooth damage. The wrong pinion clearance on starter drives of the over-running clutch type leads to poor meshing of the pinion and ring gear and too rapid tooth wear.

A less common cause of noise with either type of drive is a bent starter armature shaft. When this shaft is bent, the pinion gear alternately binds and then only partly meshes with the ring gear. Most manufacturers specify a maximum of .003″ radial run-out on the armature shaft.

Fig. 71 Folo-Thru starter drive with Bendix spring

Fig. 72 Folo-Thru starter drive without Bendix spring

Fig. 73 Barrel type Bendix drive

Fig. 74 Measuring overrunning clutch drive stop clearance. Do not compress anti-drift spring as this will give an incorrect clearance. If clearance is not present there is danger of the drive housing being broken as gear or collar slams back against it

Fig. 75 Adjusting pinion clearance on overrunning clutch motor with an exposed solenoid having a non-adjustable plunger stud

Fig. 76 Overrunning clutch motor equipped with adjustable plunger stud for adjusting pinion clearance

When Clutch Drive Fails

The over-running clutch type drive seldom becomes worn that they fail to engage since they are directly activated by a fork and lever, Fig. 70. The only thing that is likely to happen is that, once engaged, it will not turn the engine because the clutch itself is worn out. A much more frequent difficulty and one that rapidly wears ring gear and teeth is partial engagement. Proper meshing of the pinion is controlled by the end clearance between the pinion gear and the starter housing or the pinion stop, if one is used.

The clearance is set with the starter off the vehicle and with the drive in the engaged position. While it is not feasible to list the clearances for all starters used on all trucks, the idea is to have enough clearance so that the drive does not slam against the end of the drive housing or pinion stop when it is engaged.

To check the clearance, supply current to the starter solenoid with the electrical connection between starter and solenoid removed. Supplying current to the solenoid but not the starter will prevent the starter from rotating during the test. Take out all slack by pushing lightly on the starter drive clutch housing while inserting the proper thickness feeler gauge between pinion and housing or pinion stop, Fig. 74.

On a number of late model starters, starting with 1957, the solenoids are completely enclosed in the starter housing and the pinion clearance is not adjustable. If the clearance is not correct, the starter must be disassembled and checked for excessive wear of solenoid linkage, shift lever mechanism, or improper assembly of parts.

On starters where the solenoid is exposed, the clearance can be adjusted either by loosening the screws holding the solenoid to the starter and moving the solenoid forward and backward, Fig. 75, or by screwing or unscrewing the link attached to the solenoid plunger, Fig. 76.

Failure of the over-running clutch drive to disengage is usually caused by binding between the armature shaft and the drive. If the drive, particularly the clutch, shows signs of overheating, it indicates that it is not disengaging immediately after the engine starts. If the clutch is forced to over-run too long, it overheats and turns a bluish color. For the cause of the binding, look for rust or gum between the armature shaft and the drive, or for burred splines. Excess oil on the drive will lead to gumming, and inadequate air circulation in the flywheel housing will cause rust.

Over-running clutch drives cannot be overhauled in the field so they must be replaced. In cleaning, never soak them in a solvent because the solvent may enter the clutch and dissolve the sealed-in lubricant. Wipe them off lightly with kerosene and lubricate them sparingly with SAE 10 or 10W oil.

When Bendix Drive Fails

When a Bendix drive doesn't engage the cause usually is one of three things: either the drive spring is broken, one of the drive spring bolts has sheared off, or the screwshaft threads won't allow the pinion to travel toward the flywheel. In the first two cases, remove the drive by unscrewing the set screw under the last coil of the drive spring and replace the broken parts. Gummed or rusty screwshaft threads are fairly common causes of Bendix drive failure and are easily cleaned with a little kerosene or steel wool, depending on the trouble. Here again, as in the case of over-running clutch drives, use light oil sparingly, and be sure the flywheel housing has adequate ventilation. There is usually a breather hole in the bottom of the flywheel housing which should be kept open.

The failure of a Bendix drive to disengage or to mesh properly is most often caused by gummed or rusty screwshaft threads. When this is not true, look for mechanical failure within the drive itself.

Bendix Folo-Thru Drive

This type of drive, Figs. 71, 72, is in wide use on late model starters. It incorporates a device that keeps the pinion engaged to the flywheel until the engine reaches a specified rpm. When replacing one of these drives, be sure that you have the correct drive for the vehicle. The drives are rated differently and the correct one must be used for the vehicle being serviced. The Folo-Thru, incidentally, is not supposed to be repaired in the field because of the danger of incorrectly assembling the carefully calibrated springs in the pinion head.

AIR STARTING MOTOR

The principle components of the "Startaire" assembly are a multi-vane type air rotor, a reduction gear assembly, and a friction clutch type drive. Compressed air in the correct volume and pressure range is used to provide the necessary cranking power. Fig. 77 shows an exploded view of an air cranking motor.

The motors are available in two sizes. Model 17 delivers approximately 17 horsepower at 100 psi air pressure with a pinion rpm of 2300. In general, model 17 cranks all engines up to approximately 1100 cubic inch displacement. Model 30 delivers approximately 30 horsepower at 100 psi air pressure with a pinion rpm of 2000. It is normally used on engines of 1100 cubic inch displacement or more.

Fig. 78 shows the various devices used in a "Startaire" installation. A pressure protection valve is used in the air supply line to protect the basic air system on the vehicle against complete loss of air during starting operation. A rubber seated single check valve permits maintenance of the Startaire system as a self-contained system in which leakage can be minimized. A control valve and air pressure gauge registering air pressures in the air starting system are in-

Fig. 77 "Startaire" air cranking motor

stalled close to the driver's position. An air starting valve which opens or closes the air line between the starter reservoir and motor, as controlled by the control valve, is mounted on or close to the motor as possible. The motor is installed on the engine in the usual location provided for starting motors. One or two reservoirs are installed in the system to provide a sufficient volume of compressed air to the system. A tire valve, tire chuck and hose coupling are provided to replenish the system from an outside source should it be required.

Operation

For operation, 100 psi or more should register on the air starter system air gauge. Before starting the engine, be sure that all engine adjustments and prior starting procedures are carried out. Depress the knob on the control valve. This action allows air to turn the motor and engage the flywheel. The control valve knob should be kept fully depressed until the engine fires. Release the control valve immediately when the engine fires to allow the drive gear to disengage the flywheel.

Preventive Maintenance

1. Daily or as often as necessary, drain the reservoir to be sure clean dry air is delivered to the motor.
2. Monthly or about every 5000 miles of service, remove pipe plug or grease fitting at air inlet port or air inlet fitting at the motor and inject ½ pint of kerosene into the rotor assembly before operating the motor. *Caution: Do not over-lubricate. Over-lubrication or use of lubricants of heavy consistency can cause improper operation. Do not perform the above flushing operation indoors as the kerosene will be discharged at the exhaust outlet with the first start. Also be certain that there is no open flame in the vicinity to ignite the exhausted kerosene.*
3. Check to see that the motor mounting is secure to the flywheel housing. Check all air lines and valves in the system for leakage.
4. Test the operation of the motor. The unit should turn over the engine quickly and at high revolutions per minute. Be sure that air pressure and volume are correct for motor requirements in making this test.
5. To make a leakage test, first see that the system is fully charged and the control valve is in fully released position. Then check to be sure there is no measurable leakage at the exhaust port of motor, at control valve knob, at tire valve, or at other possible leakage points in the system.
6. Periodically check all other devices, fittings and air lines to be sure they are tight.

Remove & Install Motor

1. Disconnect air line at control valve on Model 17 or air line at motor on Model 30.
2. On Model 17, remove motor control valve.
3. Unfasten motor housing from flywheel housing and lift out motor.
4. Reverse removal procedure to install.

Disassemble Motor

1. After covering inlet and exhaust ports, clean the exterior of the motor.
2. The original position of the mating parts should be marked. *This is important because if the rotor housing is turned end for end when reassembled, the motor will rotate in the opposite direction, the pinion will not engage and the motor could rotate at dangerous speeds.*
3. Remove drive unit housing.
4. Remove drive unit by pulling off splines of driven shaft, Fig. 79. If necessary to replace sleeve bearing in drive housing, remove oil wick and press out bearing.
5. When disassembling Model 30, remove set screw in clutch to permit removal of drive unit from driven shaft, Fig. 80. This unit contains a spring at the end of the driven shaft. In Model 30, if it is necessary to replace the needle bearing in drive housing, drive off end cap and press out bearing.
6. Remove spacer from driven shaft on Model 17.
7. Remove capscrews from cover and remove cover, driven shaft and gear, Figs. 81 and 82.
8. Release lockwasher on driven gear and remove lock nut. Use puller to remove gear from driven shaft.
9. For Model 17, remove key and press driven shaft out of bearing. Remove snap ring and press bearing from gear case cover.

Fig. 78 Typical air starter installation

10. For Model 30, remove capscrews from bearing retainer plate and press bearing and shaft from cover after which press bearing from driven shaft.
11. Remove capscrews securing gear case to main housing, including the two capscrews inside the case.
12. Before removing gear case on Model 17, remove lock wire inside case. Then remove gear.
13. Remove snap ring from roller bearing and press out bearing which is a sliding fit in case.

Removing Model 17 Rotor

1. Remove gear end plate and rotor from housing. Dowels in main case position end plates correctly.
2. When removing rotor from main housing, inner race of roller bearing remains on rotor shaft. Do not remove it unless bearing is to be replaced.
3. Remove rotor vanes to protect them from damage.
4. Remove lock nut and take off drive gear from rotor shaft with the aid of a gear puller.
5. Remove key from rotor shaft and press rotor from bearing and gear end plate, using an arbor press.
6. Rotor and shaft are serviced as a unit. *A spacer is pressed on each rotor shaft. Do not remove spacer unless replacement is required. If roto is to be reassembled using the same parts, the shims located between the spacer on the gear end of the rotor shaft and bearing inner race can be reused if not damaged.* Remove snap ring in gear end plate. Bearing is a light press fit in plate.
7. Remove plain end plate cover.
8. Remove plain end plate from housing and press out bearing.

Removing Model 30 Rotor

1. After removing drive gear from rotor shaft with a gear puller, remove gear end plate and bearing from rotor shaft. There are dowels on end plate for positioning plate correctly.
2. Remove snap ring holding roller bearing in gear end plate. Bearing is a light press fit in plate and can easily be removed.
3. Bearing inner race normally remains on shaft. Do not remove it unless a new bearing is required.
4. Remove plain end plate cover.
5. Remove end plate from main housing and lift end plate and rotor as a unit out of case.
6. Remove rotor vanes to protect them from damage. Release lockwasher and remove lock nut. Carefully press rotor from end plate or use a gear puller to remove end plate from rotor. Bearing is a light press fit in end plate. *Do not misplace or damage shims between rotor shaft shoulder and bearing inner race because the same shims can be used again for reassembly if the same parts are to be reused. The rotor and shaft are serviced as a unit only.*

Inspection of Parts

1. Clean and inspect all parts. Any broken or excessively worn parts must be replaced with new ones.
2. Inspect rotor, housing and end plates for cracks, abrasions, wear spots or build-up of foreign material. Cracked castings must be replaced. Rough or worn spots can sometimes be smoothed out with fine emery cloth. Deposits of gum, carbon, or other foreign material must be removed. Wash and dry all parts.
3. Rotor vanes should be inspected for cracks and wear and should normally be replaced.
4. Gears should be replaced if excessively worn or if teeth are broken.
5. For Model 30 the gear splines should be a light press fit on shaft splines. If fit is loose, replace parts.
6. Broken seal rings must be replaced.
7. Seal ring bores in end plates should be checked for excessive wear or roughness.
8. Seal ring grooves should be checked for visible wear.
9. Bearings should be checked for visible wear and replaced if necessary.
10. New gaskets should be used when reassembling.

Fig. 79 Drive end and housing. Model 17

Fig. 80 Drive end and housing. Model 30

Fig. 81 Cover, shaft and gear. Model 17

Fig. 82 Cover, shaft and gear. Model 30

Reassemble Model 17 Rotor

1. Install spacers and seal rings on rotor shaft. Press roller bearing on rotor shaft and install snap ring. Press bearing into gear end plate and replace bearing lock wire.
2. Place shims on gear end of rotor shaft. If same parts are being reused, use same shims if undamaged, as originally removed. If new parts are being used, use .015" of shims for

Fig. 83 Rotor and gear end plate. Model 17

Fig. 86 Cover, driven shaft and gear parts. Model 17

Fig. 84 Checking clearance between rotor and end plate. Model 17

Fig. 85 Installing vanes. Model 17

initial installation, subject to adjustment as given below.

3. Press bearing and gear end plate on rotor shaft, Fig. 83. Install key, drive gear and locknut on rotor shaft.
4. Check clearance between rotor and gear end plate. Clearance should be .002 to .003″, Fig. 84. Shims of .002, .003 and .005″ are available for adjustment.
5. After obtaining proper clearance, install rotor and gear end plate in main housing.
6. Install valves in rotor through open end of housing, Fig. 85. Install bearing in plain end plate and apply end plate to main housing, using care to avoid breaking seal ring.
7. Install capscrews and, using a new gasket, fill cover half full of ball and roller bearing grease and install cover.
8. Install bearing and snap ring in gear case. Use a new gasket and install gear case. After installing capscrews, insert lock wire.
9. Press bearing on driven shaft with its seal facing spline end of shaft. Install key, driven gear, lockwasher and lock nut.
10. Install driven shaft, bearing and gear assembly in cover and install snap ring, Fig. 86. Before assembling cover to gear case, place about 6 ounces of general purpose grease in gear case. Use a new gasket and install cover, shaft and gear in case.
11. Install spacer over driven shaft and install drive unit on shaft.
12. If the sleeve bearing in end of drive unit has been removed, press new bearing into housing flush with end face and finish inside diameter to .751-.752″ concentric with drive housing pilot diameter. If finishing tools are not available and bearing is worn, replace drive housing assembly.
13. Install oil wick after soaking it in SAE No. 10 engine oil. Install drive unit to gear case cover.

Fig. 88 Checking clearance between rotor and end plate. Model 30

Fig. 89 Installing vanes. Model 30

Fig. 87 Rotor and gear end plate. Model 30

Fig. 90 Cover, driven shaft and gear parts. Model 30

Reassemble Model 30 Motor

1. Install bearing in plain end plate, and seal rings on rotor shaft.
2. Install bearing on rotor shaft.
3. Install spacer shims on plain end rotor shaft, Fig. 87. If new parts are being used, start with about .009″ shim thickness for initial installation subject to adjustment as given below.
4. Press bearing and plain end plate over rotor shaft, using care to avoid breaking seal ring. Install lockwasher and lock nut. Do not flatten lockwasher until .003″ end clearance between rotor and plain end plate is obtained.
5. Install new gasket between small cover and end plate and install cover temporarily. Check clearance as shown in Fig. 88. Adjust as necessary to obtain .003″ clearance between rotor shaft shoulder and bearing inner race. Shims of .002, .003 and .005″ thicknesses are available for adjustment.
6. After clearance is obtained, remove small cover and fill it half full with bearing grease and reinstall cover.
7. Install rotor and plain end plate on main housing. Install rotor vanes through open gear end of housing, Fig. 89. Press bearing into gear end plate and install snap ring.
8. Install gear end plate to main housing, using care to avoid breaking seal ring.
9. Install gear on rotor shaft. Install new lockwasher and pull gear into position and install lock nut.
10. Press roller bearing in gear, install washer and snap ring, Fig. 90.
11. Using new gasket between end plate and gear case, install gear case.
12. Press bearing on driven shaft with its seal facing drive unit. Install bearing and shaft in cover, and bearing retainer plate, Fig. 90.
13. Press driven gear over splined end of shaft and install lockwasher and lock nut.
14. Place about 8 ounces of general purpose grease in gear case and install case. Using a new gasket, install cover and gear sub-assembly to gear case.
15. Install two keys and drive unit on driven shaft after installing spring between end of driven shaft and drive unit. Install and tighten set screw in drive unit. Install needle bearing in housing flush with drive face. Fill end cap half full with bearing grease before pressing into place.

STARTING SWITCHES

MAGNETIC AND SOLENOID SWITCHES are designed to perform mechanical jobs electromagnetically such as closing a heavy circuit or shifting the starter drive pinion with the engine flywheel ring gear for cranking. Switches of this type consist basically of contacts and a winding (or windings) around a hollow cylinder containing a movable core or plunger. When the winding (or windings) is energized by the battery through an external control circuit the plunger is pulled inward, producing the necessary mechanical movement.

MAGNETIC SWITCHES

Figs. 1 and 2 illustrate two typical Delco-Remy switches. The switch shown in Fig. 1 is not designed for disassembly and must be replaced if defective.

In the switch shown in Fig. 2 the terminals are assembled into a molded terminal ring which is held in place on the switch case by the cover and screws. Gaskets on both sides of the ring seal the contact compartment as a protection against moisture and dirt. The winding assembly is not removable from the case on this unit although the contact disk, plunger and plunger return spring can be removed after the cover is taken off.

Fig. 3 is a heavy duty magnetic switch. It is completely serviceable and easy to disassemble and assemble. To disassemble, remove the four terminal plate nuts and washers and take off the terminal plate assembly. The contact disk may be removed by taking off the castellated nut. It is necessary to remove the spring and washers on the plunger rod only when the rod needs to be disassembled. To remove the plunger, unscrew the large metal cover, take out the cotter pin in the plunger shaft, remove the spring retainer washer and spring, and withdraw the plunger. The winding and switch case is an integral assembly. The only parts that can be removed are the switch terminals. Before removing the switch terminals, the winding leads must be unsoldered from the terminal studs. Whenever the switch is disassembled, upon reassembly, locate the contact disk properly by turning the castellated nut in or out as required to obtain the dimension shown in Fig. 3 between the contact disk and edge of housing.

SOLENOID SWITCHES

The solenoid switch on a cranking motor not only closes the circuit between the battery and the cranking motor but also shifts the drive pinion into mesh with the engine flywheel ring gear. This is done by means of a linkage between the solenoid switch plunger and the shaft lever on the cranking motor. Some linkages are adjustable while others are

Fig. 1 End and sectional views of a typical magnetic switch

Fig. 2 End and sectional views of a sealed type magnetic switch which uses gaskets to seal the contact compartment

Fig. 3 Sectional view of heavy duty sealed type magnetic switch. To adjust the position of the contact disk, turn the nut on the disk in or out as required to obtain the dimension shown

not. The linkage is not adjustable on the type shown in Fig. 4 but adjustment of the entire assembly is made by moving the switch on the motor frame.

Fig. 4 shows two views of a solenoid switch used on vehicles with 12-volt systems. Like other solenoid switches, this type is energized by the battery through a separate starting switch. Note, however, that the switch includes an additional small terminal and contact finger. This terminal has no functional duty in relation to the switch, but is used to complete a special ignition circuit during the cranking cycle only. When the solenoid is in cranking position, the finger touches the contact disk and provides a direct circuit between the battery and ignition coil.

Fig. 5 is an exploded view of the 12-volt solenoid switch shown in Fig. 4. When reassembling the switch the contact finger should be adjusted to touch the contact disk before the disk makes contact with the main switch terminals. There should be $\frac{1}{16}''$ to $\frac{3}{32}''$ clearance between the contact disk and the main terminals when the finger touches.

Fig. 4 End and sectional views of solenoid switch. The additional terminal and contact finger are used on 12-volt passenger car applications

Fig. 5 Exploded view of solenoid switch shown in Fig. 4

Fig. 6 Wiring circuit of typical solenoid switch

Fig. 7 Exploded view of heavy duty type solenoid used with Dyer drive cranking motor

Fig. 6 is a wiring circuit of a typical solenoid switch. There are two windings in the solenoid: a pull-in winding (shown as dashes) and a hold-in winding (shown dotted). Both windings are energized when the external control switch is closed. They produce a magnetic field which pulls the plunger in so that the drive pinion is shifted into mesh, and the main contacts in the solenoid switch are closed to connect the battery directly to the cranking motor. Closing the main switch contacts shorts out the pull-in winding since this winding is connected across the main contacts. The magnetism produced by the hold-in winding is sufficient to hold the plunger in, and shorting out the pull-in winding reduces drain on the battery. When the control switch is opened, it disconnects the hold-in winding from the battery. When the hold-in winding is disconnected from the battery, the shift lever spring withdraws the plunger from the solenoid, opening the solenoid switch contacts and at the same time withdrawing the drive pinion from mesh. Proper operation of the switch depends on maintaining a definite balance between the magnetic strength of the pull-in and hold-in windings.

This balance is established in the design by the size of the wire and the number of turns specified. *An open circuit in the hold-in winding or attempts to crank with a discharged battery will cause the switch to chatter.*

To disassemble the solenoid, remove nuts, washers and insulators from the switch terminal and battery terminal. Remove cover and take out the contact disk assembly.

When the solenoid has been removed from the starter motor for repair or replacement, the linkage must be adjusted to provide the correct pinion clearance or pinion travel when the solenoid is remounted on the motor. Some solenoids equipped with relays have an adjustable plunger stud but others must be moved on the motor

Fig. 8 End and sectional views of a Delco-Remy solenoid-operated series-parallel switch. In the end view the cover has been removed so the terminal plate assembly can be seen

Fig. 9 Wiring diagram of a mechanically-operated series-parallel switch and cranking motor solenoid. This diagram shows the series-parallel switch completing the parallel connections between the batteries for normal operation of the vehicle's electrical equipment on 12 volts

Fig. 10 This diagram shows a (solenoid-operated) series-parallel switch completing the series connections between batteries so 24 volts are imposed on cranking motor

frame to adjust pinion travel. While it is not feasible to tabulate the adjustment specifications for all starters likely to be found on trucks, the object of the adjustment is to prevent the drive from slamming against the drive housing.

Solenoid on Dyer Drive Starting Motor

Fig. 7 is an exploded view of this type of solenoid switch. Disassembly of the switch is made by removing the screws or nuts attaching the terminal plate assembly. The contact disk can be detached from the plunger and rod assembly by removing the castellated nut. The contact disk may sometimes require removal so that its face can be wire-brushed to remove corrosion.

On reassembly, the castellated nut should be tightened down so that the face of the disk is $1\frac{1}{32}''$ below the edge of the housing with the plunger in the retracted position. After assembly is completed, fill the bushing in the terminal plate through which the lead passes (where present) with sealing material to prevent entrance of dirt.

DELCO-REMY SERIES-PARALLEL SWITCHES

On Diesel and similar heavy-duty engines, cranking requirements are high and consequently it is desirable to use higher voltage cranking motors so that adequate cranking performance will be obtained. The series-parallel switch makes it possible to use two 12-volt batteries which are connected in parallel for normal operating conditions after the engine is started, but which are connected in series by means of the series-parallel switch to provide 24 volts for the cranking motor. Likewise, two 6-volt batteries can be connected either in parallel or in series to provide a 6-12 volt system.

Fig. 8 shows the construction of a solenoid-operated series-parallel switch. Mechanically-operated series-parallel switches are also used. In both types, however, the switch incorporates a heavy copper contact disk and heavy tungsten-faced main terminals which resist the effects of the arcs that occur when the circuits are broken. The main cranking current is carried through these contacts and terminals. In addition there are contacts in the terminal plate which completes the parallel connections between the batteries for normal operation and also complete the connections that energize the cranking motor solenoid in the cranking position.

Fig. 9 is the wiring circuit of a (mechanically-operated) series-parallel system during normal operation of the vehicle. The main charging circuit is shown as a solid line. The current from the generator splits at the —A terminal, half of it going to the left-hand battery (dashed lines) and the other half going to the right-hand battery (dotted lines). Note that there are two circuit breakers or fuses in the right-hand battery circuit. Note also that an optional ammeter, as indicated, may be located in either of the two positions. The position in the —B to cranking motor circuit is preferable, however, since this circuit carries only the charging current while the other circuit (+A to "ground") must also carry the solenoid energizing current.

An ammeter sufficiently heavy to carry the solenoid current is generally unsatisfactory for reading small charging currents. In either position, the ammeter will indicate how much current is entering the right-hand battery, and if this is subtracted from the total shown in the main ammeter, the difference will be that which is entering the left-hand battery.

Fig. 10 illustrates the circuits during

Fig. 11 Same as Fig. 10 except with magnetic type starter switch

the cranking action when the series-parallel switch main contacts are closed (note that this diagram shows a solenoid-operated series-parallel switch). The series connections between the two batteries and the cranking motor are shown as a solid line, while the cranking motor solenoid circuit is shown as a dashed line.

As the switch is operated the solenoid plunger (or push rod in a mechanically-operated switch) strikes a small plunger in the contact plate assembly, causing the small contacts to be actuated so that the parallel connections between the two batteries are broken. Then the main contact disk connects the two main switch terminals (−A and +B); and as the small plunger completes its travel it connects the cranking solenoid through ground through the SW terminal (this circuit is shown as a dashed line). Now the cranking motor solenoid operates and closes its contacts to complete the series connections through the cranking motor so that the motor operates.

After cranking has been accomplished and the series-parallel switch is released, the two batteries again become connected in parallel to provide 12-volt operation of the equipment.

In the mechanically-operated switch, Fig. 9, a quick-break mechanism, consisting of a pair of triggers and a cam, causes the contact disk to be snapped away from the stationary contacts very quickly so that there is a very small amount of arcing.

Fig. 11 illustrates a solenoid-operated series-parallel switch used in conjunction with a cranking motor magnetic type switch. Figs. 12 and 13 are exploded views of the mechanical switch, while Fig. 14 is an exploded view of the solenoid-operated switch. These pictures can be used as guides whenever disassembly is required.

DELCO-REMY SPLASHPROOF SERIES-PARALLEL & COMBINED SERIES-PARALLEL & MAGNETIC SWITCHES

Fig. 15 illustrates a low weight series-parallel switch and Fig. 16 pictures the combined series-parallel and magnetic switch of the same type construction. The switch shown in Fig. 15 can be used with either a solenoid or separate magnetic switch controlled starting motor. The switch shown in Fig. 16 is only used with a magnetic switch controlled starting motor and incorporates the magnetic switch with the series-parallel switch into the same splashproof container.

Series-Parallel Switch Used With Solenoid Operated Motor

Fig. 17 is a schematic wiring circuit of the series-parallel system in connection with the solenoid operated motor during the cranking operation. The sequence

Fig. 12 Disassembled view of mechanically-operated series-parallel switch

Fig. 13 Disassembled view of terminal plate assembly of switch shown in Fig. 12

that takes place as the switch closes is as follows:

As the starting switch is closed, the solenoid coil within the series-parallel switch is energized, creating sufficient magnetic force to attract the series-parallel switch plunger. Movement of the plunger then closes the two main switch terminals and connects the two batteries in series with the motor. At the same time, the starter solenoid coil circuit is completed by a set of points mechanically closed by the series-parallel switch plunger. This completes the battery-to-starting motor circuit and allows cranking to take place.

After cranking has been accomplished and the starting switch is released, the two batteries again become connected in parallel with the series-parallel switch in its "at rest" position. This allows operation of the rest of the vehicle's electrical equipment at a system voltage of 12 volts. Note that there are two circuit breakers or fuses in the circuit of the "B" battery. These should be used in the location shown. The fuse capacity should be 50% of the generator rated output.

Series-Parallel Switch Used With Magnetic Switch Operated Motor

Fig. 18 is the schematic wiring circuit of this system. The position of the switch is that found in normal operation of the vehicle. The current from the generator divides at the terminal of the series-parallel switch, half of it going to the "A" battery, with the other half of the current going to the "B" battery through the series-parallel switch. Note that an optional ammeter, as indicated, may be located in either of two positions. The preferred location is shown since this circuit carries only the charging current while the other circuit must also carry the magnetic switch energizing current. An ammeter sufficiently heavy to carry the magnetic switch current is generally unsatisfactory for reading small charging currents. In either position, the ammeter will indicate how much current is entering the battery to the right, and if this is subtracted from the total shown on the main ammeter, the difference will be that which is entering the battery to the left.

Combination Series-Parallel Magnetic Switch Used With Bendix Drive Motor

Fig. 19 is a schematic wiring circuit of

Fig. 14 Disassembled view of solenoid-operated series-parallel switch

Fig. 15 End and sectional view of Delco-Remy splashproof solenoid operated series-parallel switch

this system. As the starting switch is closed, the solenoid coil within the series-parallel switch is energized, creating sufficient magnetic force to attract the series-parallel switch plunger. The movement of the plunger then joins the two sets of large terminals. This connects both batteries in series with the cranking motor in order that 24 volts can be supplied for starting motor operation.

Fig. 20 shows the same switch after the starting switch is released and the series-parallel switch is in its "at rest" or charging position.

WIRING INSTALLATION FOR SERIES-PARALLEL SWITCHES

Due to the high voltage of the starting circuit and the great amount of power

Fig. 17 Circuit diagram of series-parallel system with switch completing series connections between batteries for 24-volt starting motor operation. The motor is operated and controlled by a solenoid

Fig. 18 Circuit diagram of series-parallel system with switch completing parallel connections between batteries for normal operation of vehicle electrical equipment at 12 volts. The starting motor is operated and controlled by a separately mounted magnetic switch

Fig. 16 End and sectional view of Delco-Remy splashproof solenoid operated combined series-parallel and magnetic switch

available from the two batteries, it is essential that every precaution be taken to avoid short circuits or grounds. All wires should be of sufficient size to carry the electrical load to which they are subjected without overheating. Stranded wire and cable should be used throughout to reduce the possibility of breakage due to vibration. All connections should be clean and tight and all terminal clips should be soldered to wires or cables.

Only rosin flux should be used to solder electrical connections. Acid flux should never be used. All wires should be adequately insulated and supported at enough points to prevent movement and consequent chafing through the insulation. It is desirable that all terminals and clips, which are ordinarily left exposed, be protected by insulation. Thus, rubber boots, rubber tape or friction tape and shellac should be applied to cover all exposed terminals and clips. This will prevent accidental grounding of an exposed terminal which could cause serious damage to the system.

Fig. 19 Circuit diagram of combination series-parallel and magnetic switch completing series connections between batteries for 24-volt starting motor operation

Fig. 20 Circuit diagram of combination series-parallel and magnetic switch completing parallel connections between batteries for normal operation of vehicle electrical equipment at 12 volts

USE OF GLOW PLUGS FOR STARTING

On some applications, glow plugs are used to provide some initial heating so that starting can be facilitated. The heater coil and glow plug circuit should be connected to the +B terminal and a quick-break push button switch installed between the SW terminal of the series-parallel switch and the SW terminal of the cranking motor solenoid. Closing the series-parallel switch supplies current to the heater coil and glow plugs. After the proper heating interval, cranking is then accomplished by closing the quick-break push button switch in the cranking motor-solenoid circuit.

BATTERY CARE

For the best performance of the electrical system in which the series-parallel type switch is used, it is recommended that the "A" and "B" batteries be of the same capacity, size, age and manufacture. This will assure both batteries of receiving approximately equal charging rates and the danger of overcharging one battery and undercharging the other will be reduced.

Since the electrical loads on most vehicles are tapped off of one battery, it is recommended that periodically the two batteries should be switched in position. This will lessen the possibility of one battery becoming cycled with resultant positive plate shed which can cause unequal battery capacities.

DASH GAUGES

KING-SEELEY CONSTANT VOLTAGE DASH GAUGES

First introduced on some 1957 vehicles, the constant voltage system incorporates a voltage regulator as well as "senders" that are different from those used in previous systems, Fig. 1A. The new system can easily be tested with a voltmeter having a range up to 15 volts and with a fuel-gauge sending unit.

Responsible for the greater ease of testing is the greater simplicity of the new system. Essentially, it consists, in addition to the new-type senders, of a voltage regulator which changes the variable input from the car battery and charging system to a constant output of the gauges. When the ignition is turned on, the regulator current flows through a heating coil which encircles a bimetallic arm. Resulting heat causes the arm to bend and separate the contacts. Repeated making and breaking of the circuit supplies current at a pulsating 5 volt pressure to the gauges.

Senders for the fuel and oil-pressure gauges are rheostats. In the fuel-tank unit, the sliding contact brings full resistance into the circuit when the tank is empty and only a small amount of current flows through the dash-gauge heating coil. The bimetallic arm deflects the gauge pointer to "Empty." As the tank fills, the float arm moves the contact, decreasing resistance. As more current flows to the dash unit heating coil the pointer deflects toward "Full."

In the oil line, a contact, attached to the diaphragm, moves as pressure increases or decreases, varying the resistance in the circuit, and deflecting the gauge needle accordingly.

The sender for the temperature gauge contains an element in which resistance to the flow of electrical current increases with cold. As the engine warms up, resistance falls and the fuller flow of current to the gauge moves the pointer toward "Hot."

Fig. 1A King-Seeley constant-voltage system with units enlarged to show their construction

Trouble Shooting

When trouble develops, you can quickly put your finger on the cause through the use of the voltmeter and the fuel-gauge sending unit already mentioned. The latter should have a short ground lead and clip.

A word of caution about grounding: When testing or making replacement of a unit under the dash, be careful not to ground the wires to the gauges, sending units or regulator. A full flow of current through the regulator to ground will burn out this unit.

All the trouble that can develop in a constant-voltage gauge system falls into the following four distinct classes: 1. All gauges read too high; 2. All gauges read at high limit; 3. All gauges read too low; 4. One gauge is inaccurate or erratic.

When All Gauges Read Too High

When all gauges read too high, you will usually find that the voltage regulator is not properly grounded. To be sure, make a quick check with a jumper connected from the regulator case to the sheet metal of the instrument panel. Clean the mounting area to provide a good ground.

When All Gauges Read At High Limit

When all gauges read at the maximum of the needle travel, look for the trouble in stuck points or an open winding in the heating coil in the voltage regulator.

In checking for this trouble, connect the voltmeter to the regulator output terminal and to ground. This will show the output voltage of the regulator. If output shows a steady unregulated voltage equal to the battery voltage, the regulator is defective and should be replaced. A normally operating regulator

Fig. 1 AC electric fuel gauge

Fig. 2 Showing use of spare tank unit to check operation of dash unit

will cause the voltmeter needle to fluctuate between zero and 7 volts with a 12 volt input.

(While this method does not give an absolutely accurate voltmeter reading, it does indicate whether the regulator is functioning and can be relied upon as a quick service test.)

When All Gauges Read Too Low

There are three possible reasons for all gauges to read too low. Regulator input may be less than the required 5.5 volts, the circuit to regulator may be open or there may be an open circuit in the regulator itself.

This fault is quite simple to check. Test the input to regulator. If battery voltage is normal, regulator is defective and must be replaced.

Fig. 1B When tank is used to test temperature gauge, raising float through arc should swing needle of dash unit over toward "hot" side

Single Gauge Trouble

When only one gauge is inaccurate or erratic, the trouble is simple to trace. The cause can only be a loose connection, poor ground, or a defective dash gauge or sending unit.

To pinpoint the trouble, first disconnect the wire from terminal on fuel-level, oil-pressure or temperature sender unit. Connect the wire to the terminal on a new gas tank unit and ground the unit housing with a jumper, Fig. 1B.

With the float in the "Empty" position and the ignition switch turned on, the gauge should read at the low end of the scale. Move the float to the "Full" position, allow the gauge a minute to react and the panel indicator should swing to the top of the scale. If the indicator responds correctly, both the wire to the gauge and the gauge are normal and the sending unit is either defective or not properly grounded.

When a suspected tank unit is being tested, it must be grounded to the tank and the tank to the body and frame. If a jumper wire connected between the tank unit housing and the frame or body does not restore normal gauge action, replace the defective tank unit.

If the indicator does not respond accurately, disconnect the lead wire to the indicator and make a direct connection of the new tank unit to the indicator. If the "Empty" and "Full" tests now give normal indicator action, repair or replace the lead wire. If the indicator does not register accurately, replace it.

AC FUEL GAUGE

The gauge consists of two units: (1) The indicating or dash unit which is mounted on the instrument panel; (2) the tank unit which is installed in the fuel tank. These two units are connected by a single wire and each unit is grounded in its respective location.

Fig. 1 shows a wiring diagram of the gauge. The dash unit consists of two coils spaced 90 degrees apart with an armature and integral pointer at the intersection of the coil axis. An inertia dampener is provided on the armature to prevent vibration on rough roads.

The tank unit consists of a housing enclosing a rheostat or resistance unit with a brush which contacts the resistance unit. This contacting brush is actuated by the float arm—movement of which is controlled by the height of the fuel in the tank. Variations in resistance (height of fuel) change the value of the indicating unit coils so that the pointer indicates fuel availability. A calibrated friction brake is included in the tank unit to prevent wave motion of the fuel in the tank from oscillating the pointer on the indicating unit.

Gauge Service

If the gauge does not give an accurate indication of the amount of fuel in the tank, check to locate the trouble as follows:

First, make a tester using an extra AC tank unit known to be in good condition. Then attach a spring terminal clip to a five-foot length of colored wire. Connect the other end of this wire to the binding post of the tank unit. Next, attach two spring terminal clips to a similar piece of black insulated wire and the tester is ready for use.

Testing Dash Unit

1. Turn off the ignition switch.
2. Disconnect one of the battery cables.
3. Disconnect the wire which leads to the tank unit.
4. Using the spring clip, connect your colored tester wire to the binding post from which the wire was removed.
5. Connect the black wire to the flange of the tester and to any convenient ground—such as the unpainted part of the instrument panel.
6. Turn on the ignition switch.
7. Connect the battery cable. Move the arm of the tester back and forth slowly, Fig. 2. If the dash unit is okay, the pointer will move from

Fig. 3 AC fuel gauge connection

Fig. 4 AUTO-LITE thermostatic fuel gauge

"Empty" to "Full" freely. If the pointer doesn't move, or only moves part way, the dash unit is defective and a new AC dash unit must be installed.

Test Wiring from Dash to Tank

1. Turn off ignition switch. Disconnect battery and reconnect wire to dash unit.
2. Follow wire from tank unit to "bayonet connection" or the terminal junction block. Disconnect the wire at this point and clean wire contacts by scraping with a knife or sandpaper, Fig. 3.
3. Attach the colored wire to the end of the wire which runs to the instrument panel. Attach the black tester wire to the car frame for a ground.
4. Connect the battery cable and turn on the ignition switch. Move the arm of the tester back and forth. If the wiring is okay, the pointer on the dash unit will move from "Empty" to "Full" freely. If the pointer doesn't move or only moves part way, the trouble is in the wire from the dash unit to the tank.
5. If the pointer does move correctly, the trouble is in the tank unit or the wire which runs from it to the "bayonet connection", Fig. 3, or terminal junction block. If the connections are all clean and tight, and there are no breaks or chafes in the wire from the bayonet connection to the tank, then a new AC tank unit must be installed.

AUTO-LITE FUEL GAUGES

Thermostatic Type

Figs. 4 and 5—With this type gauge two wires are used to connect the dash unit with the tank unit. The dash unit contains two thermostatic strips heated by resistance wires wound around the strips. The two bimetal strips that are not heated take care of variations in temperature.

The two terminals of the dash unit marked "1" and "2" are connected by separate wires to the tank unit terminals marked "1" and "2".

Movement of the float arm in the tank, due to changes in fuel level, moves a contact arm across a resistance winding in the tank unit. This varies the resistance in the windings of the dash unit, raising and lowering the temperature of the bimetal strips. The strips bend, depending upon the amount of heat they receive, moving the gauge pointer.

Due to the heating of the bimetal strips, the thermostatic type fuel gauge action is slow, and the pointer does not react to sudden changes in fuel level due to sloshing of the gasoline in the tank.

SERVICE—The gauge can be tested by using a spare tank unit known to be in good condition. The procedure is as follows:

1. Disconnect wires from terminals marked "1" and "2" on the tank unit.
2. Connect the disconnected wires to the corresponding terminals of the spare tank unit.
3. Then connect a third wire to the frame of the spare tank unit and to any good grounding point on the car.
4. Turn on ignition switch. Allow about one minute for the dash unit to heat, then operate the float arm of the spare tank unit (see Fig. 2).
5. If dash unit does not indicate correctly, install a new Auto-Lite dash unit. If dash unit works properly, the fault is in either the wiring or the tank unit.
6. If the dash unit is okay, reconnect the wires to the terminals and disconnect the wires from the tank unit. Ground the No. 1 wire and allow approximately one minute for the dash unit to reach its indication —which should be above the "Full" position. Then ground both wires and the gauge should return slowly to the "½ Full" position. If the indications are not as described it indicates a grounded or open-circuited wire which should be repaired.
7. By elimination, if the gauge operates correctly in the above tests, the tank unit can be regarded as the cause of the original inoperation.
8. When reconnecting the leads to the dash or tank units, be careful not to interchange them as this would reverse the indications.
9. Erratic or incorrect indications may be caused by a loose connection or ground in the wiring or terminals. A fluctuating pointer is usually

Fig. 5 AUTO-LITE thermostatic fuel gauge wiring diagram

Fig. 6 AUTO-LITE magnetic fuel gauge wiring diagram

caused by dirty contacts in the dash unit. Sticking pointers may be caused by a bent pointer or frame or by interference between the gauge and dash panel. Remove the gauge from the panel and inspect for a bent pointer or pointer bearings. Check to see that there is a slight amount of end play in the pointer shaft and that the pointer turns freely. Clean the contacts by drawing a strip of clean bond paper between them.

Magnetic Type

Fig. 6—The dash unit has two magnetic circuits, each having a separate winding to produce two distinct magnetic fields. One of the windings is grounded internally, and sets up a constant pull toward the "Empty" indication when the ignition switch is turned on. The other winding, called the variable field winding, is grounded through the tank unit. This winding pulls the pointer across the gauge dial to indicate the amount of fuel in the tank.

The tank unit contains a resistor and a contact arm which moves as the float moves. The tank unit case is grounded to complete the fuel gauge circuit.

The magnetic field around the variable winding changes with a change in the amount of the fuel in the tank. As the float in the tank moves from "Full" to "Empty", the strength of the magnetic field is gradually reduced. When the float moves from "Empty" to "Full," the strength of the magnetic field is increased.

The pointer is mounted on a magnetic vane which is attracted by the two lower magnetic poles and assumes a position between them depending upon the combined magnetic field. A counterweight is mounted on the pointer to bring the reading back to "Empty" whenever the ignition is turned off.

SERVICE—If the gauge does not give an accurate indication of the amount of fuel in the tank, check to locate the trouble as follows:

1. Disconnect the lead from the "GA" terminal on the back of the dash unit.
2. Turn on the ignition and the pointer should stay against left stop pin ("Empty").
3. Ground the "GA" terminal and the pointer should move to the right stop pin ("Full").
4. Check the wiring from the ignition switch to the "SW" terminal and replace the dash unit if it does not act as described.
5. Reconnect the lead to the "GA" terminal and disconnect the lead from the tank unit. The gauge should stay against the left stop pin when the ignition is turned on. If it indicates "Full", look for a ground in the wiring between the dash and tank units.
6. Ground the lead at the tank unit. If the gauge does not move to the right pin, look for open circuit in wire.

NOTE—The above tests checked for faults in the dash unit variable field winding and for opens or grounds in the connecting wires, but did not check the constant field winding or tank unit. To test these parts, proceed as follows:

1. Connect a spare tank unit, known to be in good condition, to the "GA" terminal on the dash unit and ground the tank unit case.
2. Operate the float arm manually and observe the readings. If the dash unit indications are incorrect, remove and calibrate the dash unit; if the dash unit indicates correctly, replace the tank unit.
3. If no spare tank unit is available to make this check, remove the tank unit and use it for the above check. If the dash unit constant field winding is open or grounded, the gauge will read "Full" over a large part of the float arm movement. If the tank unit is faulty, the gauge will be erratic or will not operate at all.
4. If the operation of the gauge is erratic it may indicate that there is interference with the pointer movement. Remove the dash unit and inspect the pointer and armature assembly. Straighten the pointer if it has been bent and rubs against the dial and frame. Check to make sure there is a slight amount of end play in the pointer shaft and that the bearing plates have not been bent out of alignment.
5. Make sure bearings are clean. If the adjustable bearing is loose, or after adjusting the end play, apply a drop of air drying varnish to prevent the bearing from turning. Later gauges do not have this adjustable bearing screw; the shaft being held in position between the bearing plates, the upper one being loose and held in place by the dial screws. In no case should varnish be applied to this type bearing and adjustment is not necessary.
6. To calibrate the dash gauge, remove it from the panel and mount it in the same position. Check to make sure the pointer turns easily and returns to the left hand stop (empty) from any position. The pointer should return promptly and have a very slight bank against the stop.
7. Connect the "SW" terminal on the dash unit to one battery terminal and ground the dash unit frame to the other battery terminal.
8. Connect the tank unit to the "GA" terminal and connect the tank unit case to the battery ground terminal.
9. Place the float arm in the "Full" position and turn the right hand pole shoe so that the pointer just indicates "Full."
10. Place the float in the "Empty" position and turn the left hand pole shoe to give the correct indication.
11. To rotate the pole shoes, pry the U-shaped lug on the top edge of the shoe.
12. Check the indications at the "Full", "½ full" and "Empty" positions.
13. When calibrating, it may be necessary to spread or reduce the indicator movement. This is done by bending the upper shoe to increase or decrease the air gap between the pole and armature.
14. After all adjustments are completed, apply a drop of air drying varnish to each shoe to prevent slipping.

KING-SEELEY & FORD FUEL GAUGES

Prior To 1957

Fig. 7—This type gauge consists of a receiver and sender unit. The sender, of course, is the tank unit, whereas the receiver is the dash unit.

The sender unit contains a heating coil formed around a bimetal strip, and an external float which varies the height of a grounded spring contact, which in turn increases or decreases the tension of the bimetal strip.

The receiver unit contains a similar heating coil and bimetal strip, linked to a pointer. The receiver unit is series connected to the ignition switch, and therefore, operates only when the ignition switch is turned on.

When the fuel tank is empty, the float of the tank unit is at the bottom of its movement and the two contacts are just touching. With the ignition switch turned on, current flows through the circuit and heat is generated in the heating coil, causing the bimetal strip to bend. Bending of the bimetal opens the contacts and the circuit is broken. The heating coil and bimetal then cools and the spring returns to its former position where contact is again made.

Since the heating coils of the two units are connected in series, a similar slight bending of the bimetal strip in the dash unit takes place, which is just sufficient to pull the pointer to the "Empty" position.

When the fuel tank is filled, the action of the float and eccentric shaft (some units have cams) raises the grounded contact against the insulated bimetal contact, bending the bimetal strip in the dash unit.

With the bimetal strip under tension, a greater amount of current is required to bend it sufficiently to break contact. A similar increased bending of the bimetal strip in the dash unit occurs and this action pulls the needle over the "Full" position on the dial. The cycle of opening and closing of the contacts is continuously repeated.

Because the bimetal strips heat and cool slowly, sudden changes of fuel level caused by the sloshing of gasoline in the tank are dampened and a steady reading of the average fuel level in the tank is indicated.

Service

Trouble in the units or circuits may cause the gauge to indicate "Empty" at all times or the pointer may constantly rest beyond the "Full" mark.

Fig. 7 FORD and KING-SEELEY fuel gauges (prior to 1957)

Fig. 7A Testing dash unit fuel gauge with volt-ammeter test set

Gauge Does Not Indicate

When the dash unit does not indicate the fuel level with ignition switch turned on, check the dash unit and wire to the tank unit as follows:

1. With ignition switch turned off, connect a jumper wire from the tank unit terminal to a convenient ground.
2. Turn the ignition switch on momentarily. Then if the dash unit gives an indication, the tank unit is defective and must be replaced.
3. If the dash does not show any indication after completing step 2, ground the tank-to-dash wire at the dash unit terminal.
4. Turn ignition on momentarily. If the dash unit now indicates, then the wire to the tank unit is defective and must be repaired or replaced. However, if the dash unit fails to indicate, then the dash unit is defective.

CAUTION—In making tests, be sure to turn off the ignition switch before the pointer reaches the full end of the scale, otherwise damage to the dash unit will result. A defective tank unit or wiring may have damaged the dash unit. After installing a new dash unit, observe its action after turning on the ignition switch momentarily. If the pointer moves beyond the "Full" mark, then the tank unit or wiring is defective and must be replaced.

In rare cases, a false indication of fuel level would be obtained if a leak developed in the tank unit float. If this condition is found, replace the complete tank unit.

Gauge Indicates Beyond "Full" Mark

When this condition occurs, regardless of the quantity of fuel in the tank, make the following tests to determine the source of the trouble. Before each test, be sure to turn on the ignition switch momentarily to energize the units.

1. If the tank unit is equipped with a radio condenser, disconnect the condenser. Then if the dash unit indicates correctly, the condenser is shorted and a new one should be installed.
2. The next step is to check the wiring between the gauges. Do this by disconnecting the existing wire and substitute a jumper wire between the gauges. If the dash unit now checks OK, it indicates that the wiring is defective.
3. If the wiring proved not to be the cause of the trouble, use a spare tank unit and operate the float by hand, first being sure to ground the tank unit housing. Now if the dash unit indicates correctly, the tank unit was the source of the trouble.
4. If the dash unit still fails to function properly after making the above tests, replace it with a new one.

Using Volt-Ammeter Test Set

If a volt-ammeter test set is available, perhaps it is quicker to test the dash gauge first.

1. Disconnect tank unit wire at dash gauge.
2. With ignition switch *off,* connect volt-ammeter test set and dash gauge as shown in Fig. 7A.
3. Turn rheostat knob to maximum resistance.
4. Turn ignition switch on.
5. Decrease resistance until voltmeter reads 1.5 volts. If the dash gauge is functioning properly, the fuel gauge will indicate about ½. If it does not, the gauge is defective.
6. If the dash gauge indicates properly according to the above test, then check out the radio condenser and dash-to-tank unit wiring as directed above. If these check out all right, obviously the tank unit is defective.

STEWART-WARNER FUEL GAUGE

Fig. 8.—This type gauge consists of an ammeter and rheostat. The ammeter, which is calibrated in gallons, is the dash unit and its readings are dependent on the amount of current passed to it by

Fig. 8 STEWART-WARNER fuel gauge

the float controlled rheostat—which is the tank unit. If the gauge fails to function properly, make the following tests:

1. Make sure that all wiring connections are tight and electrically secure; that the line from the tank unit to the dash unit is not grounded or open, and that the dash unit and tank unit are well grounded.
2. Disconnect the wire running from the tank to the dash unit at the tank terminal and ground it to the frame while the ignition is on. If the gauge now reads full and drops to empty when the wire is removed from the ground on the frame, the tank unit is faulty. If the dash unit behavior is not as just described when the wire is grounded to the frame and then removed, a defective dash unit is indicated.

If the tank unit is faulty, be sure to have the ignition turned off before removing it from the tank.

AC TEMPERATURE GAUGES

Vapor Pressure Type

This type gauge consists of a metal case, enclosing a dial, a frame and mechanism assembly. Hermetically attached to the frame socket is a capillary tube (connector) and immersion bulb. The immersion bulb contains a liquid, such as ether, whose vapor pressure is proportional to the temperature.

The expanded gas is directed up the capillary tube, and into the curved bourdon tube (C shaped) which has one end fastened to the mechanism frame. The applied pressure has a straightening effect on the bourdon tube and results in its free end moving outward in proportion to the pressure. Since the free end is connected to the pointer by a linkage, the bourdon tube movement is transferred to an indication on the dial. Because the vapor pressure is constant for any given temperature, the dial is calibrated directly in degrees Fahrenheit.

Fig. 9 Removing vapor pressure bulb from engine block

Service

Vapor pressure gauge troubles are of three kinds: (1) The pointer movement is sticky, jumpy or uneven. (2) The pointer does not move at all. (3) The pointer shows temperatures which are obviously incorrect.

Most automotive engines are designed to operate at temperatures between 160 and 180 degrees. Should temperature go consistently higher than normal operating temperatures, the engine may be overheating due to one or more of the following:

1. Broken or loose fan belt.
2. Collapsed radiator hose.
3. Frozen radiator.
4. Obstruction in front of radiator, such as dirt or insects.
5. Thermostat out of order.
6. Radiator pressure cap (if fitted) not operating properly.
7. Poor engine lubrication.
8. Low water level in radiator and cooling system.

After the cooling system is thoroughly checked, test the temperature gauge to make sure that nothing is wrong with it. The procedure is as follows:

1. Drain water from radiator.
2. Loosen plug which holds vapor pressure bulb in engine block.
3. Remove the vapor pressure bulb from the engine, Fig. 9.
4. Place the vapor pressure bulb in a pail of hot water, Fig. 10. Also place a thermometer which reads up to 200 degrees F. or higher, and which is reasonably accurate in the hot water. Leave them in about three minutes.
5. If the temperature gauge is okay, the pointer should register the same temperature as the thermometer.
6. If this test shows that the trouble is in the gauge itself, the entire gauge should be replaced with a new unit.
7. When reinstalling one of these gauges in the engine block, don't use a wrench with too long a handle, and don't turn the bulb down too hard. A water-tight fit is all that is needed.

AC Electric Type

This type gauge, Fig. 11, consists of a dash unit and engine unit. These two units are connected by a single wire and each unit is grounded in its respective location.

Fig. 10 Testing vapor pressure type temperature gauge

The indicating unit consists principally of two coils spaced 90 degrees apart with an armature and integral pointer at the intersection of the coil axis. An inertia dampener is provided on the armature assembly to prevent vibration of the pointer on rough roads. The dial has a scale graduated in degrees Fahrenheit.

The engine unit has no moving parts and is essentially an electrical resistor which changes resistance with changes in temperature. The unit has a high resistance value when cold and a low resistance value when hot.

The change in engine unit resistance modifies the strength of the indicating unit coils and causes proper indication of the pointer.

SERVICE—Electric temperature gauge troubles are of four kinds: (1) The pointer doesn't move when the ignition switch is turned on. (2) The pointer indicates a high temperature whether the engine is hot or cold. (3) The pointer does not show temperature accurately. (4) The pointer indicates a low temperature whether the engine is hot or cold.

In addition to the above, any of the cooling system troubles listed under va-

Fig. 11 AC electric temperature gauge wiring diagram

por pressure gauges can also affect the electrical unit.

Incorrect temperature readings are checked as follows:

1. Disconnect wire from binding post on end of engine unit.
2. Turn ignition switch on.
3. Hold end of wire away from all wires or other metal.
4. Check dash unit. The needle should point to the low mark or "100".
5. Touch the bare end of the wire to the engine block.
6. Check dash unit again. The needle should then point to over "212" or the high mark.
7. If the dash unit reads as described in steps 4 and 6, it indicates reasonable performance of the dash unit and the connecting wire. In this event, the engine unit should be checked as described below. But if the dash unit does not indicate properly, then first check the wire. If it is okay, replace the dash unit.
8. To check the engine unit, drain the water from the radiator.
9. Disconnect the wire which is attached to the engine unit, Fig. 12.
10. Loosen the engine unit and lift it out.
11. Reconnect the lead wire to the engine unit. Ground the threaded portion to a convenient point on the car with suitable wire and clamps.
12. Get a pail or other suitable receptacle and fill it with hot water. Also a thermometer having a reading of 200 degrees F. or higher which is known to be reasonably accurate. Place the threaded end of the engine unit part way down into the hot water. Place the thermometer in also. Leave them in the water for about three minutes. Do not let any water get above the threads on the engine unit as to do so may ruin the unit.
13. If the dash unit is okay, the pointer should indicate the same temperature as the thermometer. If the pointer does not indicate correctly, replace the engine unit.

AUTO-LITE TEMPERATURE GAUGES

Vapor Pressure Type

This type gauge operates and is serviced in the same manner as described for AC vapor pressure gauges.

Fig. 12 Disconnecting wire from electric type temperature gauge

Electric Type

This type gauge, Fig. 13, includes two units. The dash unit has three magnetic poles, two of which have windings. One of these windings is connected to the ignition switch and to ground and creates a steady magnetic pull toward the low mark on the scale. The other winding is also connected to the ignition switch but it is grounded by the engine unit. It creates a magnetic pull toward the maximum temperature position, the strength of which is dependent upon the amount of resistance inserted in the circuit by the engine unit.

The engine unit is actuated thermally without moving parts. The resistance unit in the engine unit is made of special metal oxides in the form of a flat disc that changes resistance as its temperature varies. When it is hot, the resistance inserted in the variable field circuit is reduced and the pointer is attracted toward the "Hot" position.

The pointer on the dash unit is mounted on a magnetic vane which is attracted by the two lower magnetic poles and assumes a position between them depending upon the combined magnetic field. A counterweight is mounted on the pointer to bring the reading back to zero whenever the ignition is turned off.

SERVICE—The procedure for testing these gauges is the same as described for the AC electric temperature gauge.

KING-SEELEY & FORD TEMPERATURE GAUGES

Prior To 1957

These units, Fig. 14, consists of a sender unit located in the cylinder head and series connected to the receiver or dash unit. The illustrations show the two engine units, one for each cylinder head on some 1949 and later Ford V8 engines. When only one sender unit is

Fig. 13 AUTO-LITE electric temperature gauge wiring diagram

Fig. 14 FORD and KING-SEELEY temperature gauges. The diagrams show the installation on 1949 and later V8 engines in which two engine units are used, one in each cylinder head

used, as in the case with an "In-Line" engine the single terminal sender unit is used.

The single terminal sender unit consists of a heating coil formed around a bimetal strip, insulated from the grounded frame. A grounded contact is attached to the frame in alignment with the bimetal contact.

The double terminal sender unit is similar in outward appearance to the single terminal unit with two terminals provided to allow series connection between the receiver unit and the single terminal unit in the opposite cylinder head. As shown in illustration, this unit consists of a bimetal strip with a contact point, insulated from a supporting frame. The frame also supports a phosphor bronze spring with a contact point in alignment with a bimetal contact, both insulated from ground.

The bimetal assemblies of both sender units are sealed in their respective waterproof casings. The receiver and sender units are both calibrated at the factory and if either one become defective, it should be replaced with a new one.

Operation

The dash unit is connected to the ignition switch and to the series connected engine unit (or units). The dash unit will indicate water temperature only when the ignition switch is turned on. When the ignition is turned off, the pointer will register at the "Hot" position. This does not indicate that the cooling system is overheated but that the pointer is at its normal at rest position.

The dash unit, operated by a heater wire on a bimetal strip, is connected to a bulb in the cylinder head (or one bulb in each cylinder head as in Fig. 14). The bulbs have similar bimetal strips as the dash unit. When the ignition is turned on, current will pass through the dash unit and the engine unit (or units). The single terminal engine unit is normally grounded. However, as the current passes through the engine unit (or units), heat is generated in the single terminal engine unit bimetal, causing it to bend and open the contact to ground. Flow of current is then stopped, permitting the bimetal to cool and return to its normal, grounded position and the cycle is again repeated.

The same amount of current passes through the dash and engine units since they are connected in series with each other. This current also causes the bimetal in the dash unit to become heated and pull the pointer over to the left or right, depending on the temperature of the water. The cycle of opening and closing of the engine unit contact points is repeated continuously.

When the temperature of the water increases, the heat from the circulating water around the single terminal engine unit supplements the heat generated by the current passing through the units,

Fig. 15 FORD and KING-SEELEY. Showing check points for testing temperature gauges when two engine units are used

reducing the amount of current necessary to cause the bimetal to draw away from the fixed contact. With less current flowing through the engine unit (or units), less current likewise flows through the dash unit and deflection or bending of the bimetal in the dash unit is lessened.

Service

When the dash unit does not register with the ignition switch turned on, check the engine unit (or units) and wires as follows:

1. With the ignition switch turned off, short out the single terminal engine unit by clipping one end of a jumper wire to its terminal and the other end to ground.
2. Turn ignition switch on momentarily. If the dash unit now gives an indication, then the single terminal engine unit is defective and must be replaced.
3. On Ford V8 engines using two engine units, check the double terminal engine unit as follows: If the dash unit does not register as in step 2, ground terminal "2" of the double terminal engine unit to which the wire connecting the single terminal unit is attached, Fig. 15. Turn the ignition switch on momentarily and observe if the dash unit registers. If it does, then the wire connecting the two engine units is defective.
4. If the dash unit does not register as in step 3, move the clip of the ground wire to terminal "3" of the double terminal engine unit. Turn the ignition switch on momentarily. If the dash unit now registers, then the double terminal engine unit is defective and must be replaced.
5. If the dash unit does not register as in step 4, ground terminal "4" at the dash unit, Fig. 15. If the dash unit registers, then the wire connecting the double terminal engine unit to the dash unit is defective. If the dash unit is still inoperative after the preceding tests, replace the dash unit.

WARNING—In making the above tests, turn off the ignition before the pointer reaches the end of the scale, otherwise the dash unit will become damaged or burned out.

AC OIL PRESSURE GAUGES

Pressure Expansion Type

This type gauge is similar in principle to the vapor-pressure type of water temperature gauge previously described. In this unit, however, oil under pressure passes from the engine unit up the connecting tube to the dash unit. As the pressure builds up it has a tendency to straighten out the C-shaped bourdon tube in the dash unit and thus move the pointer attached to the free end of the tube.

As with the water temperature gauges, engine factors should be considered when checking oil gauge operation. Engine oil should be brought to normal temperature. Pressure at idling speed will vary from 3 to 15 lbs., depending on the make of truck. Above 30 mph engine speed the gauge should show between ½ and ¾ distance across the dial.

If the gauge is jumpy, sticky or uneven in its operation it must be replaced. If it is suspected of being off its calibration, another gauge known to be accurate can be connected to the oil line and checked. If the new gauge indicates correctly, it proves that the old gauge is defective.

Occasionally the operation of the unit can be improved by using a fine wire to clear any accumulation of oxide that may plug the small hole in the oil gauge connection.

Also check the oil line from engine to gauge for leaks. Loosen the nut but do not remove the oil line at the engine block while the engine is running. If oil runs out, the trouble is in either the oil line or dash unit.

Electrical Type

This gauge, Fig. 16, consists of a dash and engine unit connected by a single wire. Each unit is grounded in its respective location.

The indicating unit consists principally of two coils spaced 90 degrees apart with an armature and integral pointer at the intersection of the coil axis. An inertia dampener is provided on the armature to prevent vibration of the pointer on rough roads. The dial has a scale graduated in pounds per square inch.

The engine unit consists of a housing enclosing a diaphragm and linkage which moves a contact over a resistance proportional to oil pressure. The change in engine unit resistance modifies the strength of the indicating unit coils and causes proper indication of the pointer.

Service

Electrical oil pressure gauges are subject to five kinds of troubles:

1. The pointer will not move when the ignition switch is on. Probable

Fig. 16 AC electric oil pressure gauge

causes are (a) defective dash unit, (b) break or poor connection between battery and dash unit, (c) dash unit not grounded.

2. The pointer indicates "high" all the time: Probable causes are (a) defective engine unit, (b) break in dash to engine unit wire, (c) engine unit improperly grounded.
3. The pointer indicates "low" all the time: Probable cause is a short to ground at engine unit terminal or in dash-to-engine unit wire.
4. The pointer never indicates low and is always too high: Probable causes are (a) loose or dirty connections, (b) defective dash unit, (c) defective engine unit.
5. The pointer never indicates high and is always too low: Probable causes are (a) partial ground at engine unit terminal or in dash-to-engine unit wire, (b) defective dash unit, (c) defective engine unit.

To locate the trouble, use the same testing apparatus pictured in Fig. 2 for testing AC fuel gauges, and proceed as follows:

1. Turn off ignition switch.
2. Disconnect one of the battery cables.
3. Disconnect the wire from the oil gauge dash unit which runs to the engine unit.
4. Using the spring clip, connect the colored tester wire to the binding post from which the wire was removed.
5. Connect the black tester wire to the flange of the tester and to any convenient ground—such as the unpainted part of the instrument panel.
6. Turn on the ignition switch.
7. Connect the battery cable. Move the arm of the tester back and forth slowly, Fig. 2. If the dash unit is okay, the pointer will move from the low mark to the high mark freely. If the pointer doesn't move, the dash unit is defective and a new one should be installed.
8. If the dash unit proves to be okay, the next step is to test the wiring between the dash and engine unit. This also can be done with the tester as follows:
9. Turn the ignition switch off and disconnect one battery cable.
10. Follow the wire from the dash to the engine unit, and disconnect the wire at the engine unit.
11. Attach the colored tester wire to the end of the wire which runs to the dash unit. Attach the black tester wire to any convenient ground, such as an unpainted part of the engine.
12. Connect the battery cable. Move the arm of the tester back and forth. If the wiring is okay, the pointer on the dash unit will move from the low mark to the high mark freely. If the pointer doesn't move, or only moves part away, the trouble is in the wire from the dash to engine unit. Repair or replace the wire.
13. If the pointer does move correctly, then the trouble is in the engine unit. If the connection at the engine unit is clean, then a new engine unit must be installed.

AUTO-LITE OIL PRESSURE GAUGES

Pressure Expansion Type

This type gauge is similar to the one described for AC and service is performed in the same manner.

Electric Type

This type gauge, Fig. 17, consists of a dash and engine unit. The dash unit has three magnetic poles, two of which have windings. One of these windings is connected to the ignition switch and to ground and creates a steady magnetic pull towards the "zero" position when the ignition switch is turned on. The other winding is also connected to the ignition switch but is grounded by the engine unit. It creates a magnetic pull toward the maximum pressure position, the strength of which is dependent upon the amount of resistance inserted in the circuit by the engine unit.

The engine unit has a resistance with a sliding contact which is actuated by the oil pressure. When pressure is applied to the diaphragm in the engine unit, resistance is shorted out.

The pointer is mounted on a magnetic vane which is attracted by the two lower magnetic poles and assumes a position between them depending upon the combined magnetic field. A counterweight is mounted on the pointer to bring the reading back to zero whenever the ignition is turned off.

Service

To test a gauge which does not give true indications of the oil pressure, make sure electricity is reaching the dash unit. This can be checked as follows: With ignition switch turned on, connect a test lamp from the "SW" terminal on the dash unit to a ground. If the lamp does not light it indicates no current is reaching the gauge, and the ignition switch, ammeter and wiring should be thoroughly inspected.

If current is reaching the gauge, disconnect the lead from the engine unit and again turn on the ignition. The pointer should stay against the left stop pin (no pressure side). Ground the engine unit lead and the pointer should stay against the right stop pin (high pressure side).

If the test results are not as described above, the source of the trouble may be found by following the same procedure outlined for AC electric oil pressure gauge, but using an Auto-Lite fuel gauge tank unit.

KING-SEELEY & FORD OIL PRESSURE GAUGES

Prior To 1957

These gauges, Fig. 18, consist of a dash unit and engine unit. The dash unit is connected to the ignition switch and in series with the engine unit. When the ignition switch is turned off, the pointer will rest at the extreme left position.

The engine unit contains a diaphragm which is deflected in proportion to the pressure of the oil in the line. When the diaphragm is deflected, an electrical circuit is closed, allowing current to flow through a heating coil wound around a bimetal strip. Heat, generated in this coil, deflects the bimetal to the point where the contact is opened. The bimetal then cools and returns to its original position, which again closes the electrical circuit. This cycle of opening and closing is repeated continuously.

The dash unit contains a similar heating coil formed around a bimetal, connected in series with the coil in the en-

Fig. 17 AUTO-LITE electric oil pressure gauge wiring diagram

gine unit. As heating takes place in the engine unit, heating also takes place in the dash unit, causing the bimetal strip in each unit to deflect simultaneously.

The pointer indicator is linked to the bimetal strip and oil pressure is indicated by the amount of deflection actuating the pointer.

Increased oil pressure causes greater deflection of the diaphragm in the engine unit, therefore a greater amount of current is required to open the heating coil circuit. This increased current is transmitted to the dash unit, causing a corresponding increased bending of the dash unit bimetal and resultant indication of increased oil pressure.

The heating coil in the engine unit is shunted by a calibrating resistor at the time of assembly to assure accuracy of the unit.

Service

If the oil pressure gauge is not functioning properly, make the following tests in the order given until the source of trouble is found. If the dash unit pointer indicates oil pressure upon turning on the ignition switch (engine not running) contacts in the engine unit may be frozen, the wire from the dash-to-engine unit may be shorted to ground, or the dash unit may be defective. If this condition existed for any length of time, it is probable that the dash unit is damaged. To check the gauge, proceed as follows:

1. Check for loose connections at the terminals of the dash and engine units and connections at the ignition switch. Inspect condition of wire from dash-to-engine units and wire from dash unit to ignition switch.
2. Remove wire from engine unit terminal. If pointer of dash unit now remains at zero position (ignition switch turned on momentarily and engine not running) then the engine unit is defective and must be replaced.
3. If the pointer still registers after completing step 1, remove the dash-to-engine unit wire at the dash unit and observe the pointer when the ignition is momentarily turned on (do not start engine). If dash unit does not register now, then the wire between the two units is grounded and must be repaired or replaced.
4. If pointer still registers after completing step 2, then the dash unit is defective and must be replaced. After installing new dash unit, check its action to make sure engine unit and wiring are satisfactory.

If dash unit does not indicate oil pressure with ignition on and engine running, connections and wiring appearing satisfactory, test as follows:

1. With ignition switch turned off, short out the engine unit at the terminal. Use a jumper wire with clips for this purpose. Clip one end to the terminal screw of the engine unit and the other end to engine ground.

Fig. 18 FORD and KING-SEELEY electric oil pressure gauge (prior to 1957)

2. Turn ignition on momentarily. If dash unit now registers, then the engine unit is defective and must be replaced.

WARNING—Turn ignition off before pointer of dash unit reaches the highest pressure mark on the scale. In this test the full voltage of the battery is placed on the dash unit and if allowed to remain for a longer period of time, the unit will burn out.

3. If the dash unit fails to register with the engine unit shorted out as in step 2, either the dash unit or the wire running to the engine unit is defective. Turn ignition switch off and check the wire by clipping one end of the jumper wire to the dash unit terminal and the other end to ground.

CAUTION—Be sure grounding wire is not connected to ignition side of dash unit.

4. Turn ignition on momentarily. If dash unit fails to register, then the dash unit is defective.
5. A defective engine unit or wiring may have damaged the dash unit. After installing a new dash unit, observe its action after turning ignition on momentarily. If the indicator moves beyond the point of normal oil pressure, the engine unit or wiring is defective and must be checked.

OIL PRESSURE WARNING LIGHT

Some late model vehicles utilize a warning light on the instrument panel in place of the conventional dash indicating gauge to warn the driver when the oil pressure is dangerously low. The warning light is wired in series with the ignition switch and the engine unit—which is an oil pressure switch.

The oil pressure switch contains a diaphragm and a set of contacts. When the ignition switch is turned on, the warning light circuit is energized and the circuit is completed through the closed contacts in the pressure switch. When the engine is started, build-up of oil pressure compresses the diaphragm, opening the contacts, thereby breaking the circuit and putting out the light.

Trouble Shooting

The oil pressure warning light should go on when the ignition is turned on. If it does not light, disconnect the wire from the engine unit and ground the wire to the frame or engine block. Then if the warning light still does not light when the ignition switch is on, replace the light bulb.

If the warning light goes on when the wire is grounded to the frame or cylinder block, the engine unit should be checked for being loose or poorly grounded. If the unit is found to be tight and properly grounded, it should be removed and a new one installed. (The presence of sealing compound on the threads of the engine unit will cause a poor ground.)

If the warning light remains lit when it normally should be out, the wire from the light to the engine unit may be grounded. To check for this condition, disconnect the wire at the engine unit and if the light remains lit a ground is indicated. If the light goes out, then the engine unit is at fault and it should be replaced.

The warning light sometimes will light up or will flicker when the engine is idling, even though the oil pressure is adequate. However the light should go out when the engine is speeded up. There is no cause for alarm in such cases; it simply means that the pressure switch is not calibrated precisely correct.

AMMETERS

Automotive ammeters indicate direction of current flow (charge or discharge) and the relative amount of current flow. The center point of the dial, Fig. 19, is the point of zero current flow and the two extremes of pointer travel indicate maximum charge and discharge. Therefore, the indicator must not be read for the amount of current charge or discharge but only for charge condition of the generating system.

The typical ammeter consists of a frame to which is attached a permanent magnet. The frame also supports an armature and pointer assembly. When no current flows through the ammeter, the magnet holds the pointer armature so that the pointer stands in the center of the dial. When current passes in either direction through the ammeter, the resulting field attracts the armature away from the affect of the permanent magnet, thus giving a reading proportional to the current strength.

Service

When the ammeter apparently fails to register correctly, there may be trouble in the wiring which connects the ammeter to the generator and battery, or in the generator and battery themselves. There are only a few simple things to check in order to find the cause:

1. Loose connections on the back of the ammeter.
2. Loose connections at the back of the ignition switch, or at the battery. (Ammeters are not grounded to the instrument panel.)

Fig. 19 Drawing of a typical ammeter or battery charge indicator

3. Spots on the wiring where the insulation has been chafed, burned or broken.

To check the connections, first tighten the two binding posts on the back of the ammeter. Then, following each wire from the ammeter, tighten all connections on the ignition switch, battery and generator. Chafed, burned or broken insulation can be found by following each ammeter wire from end to end.

After checking and repairing the wiring, tighten all connections and turn the ignition switch on. The pointer should point to the discharge side of the dial slightly. Start the engine and speed it up to about 30 mph. The pointer should then move to the charge side of the dial and its movement should be smooth.

If the pointer does not behave correctly the ammeter itself is out of order and must be replaced with a new one.

GENERATOR TELLTALE LIGHT

Some late model vehicles utilize a light on the instrument panel in place of the conventional ammeter to indicate to the driver when the generator is charging the battery. The telltale element is a panel-mounted window (usually red) behind which is mounted a small lamp bulb. The bulb lights whenever the ignition switch is turned on and the generator not charging.

Auto-Lite System

When the ignition switch is turned on the circuit is completed from the ignition switch, through the bulb, to a special terminal on the voltage regulator, to the insulated contacts on top of the circuit breaker, to the grounded strap of the circuit breaker.

As the engine is started and generator speed is increased to a car speed of approximately 10 mph, the generator develops sufficient voltage to pull down the circuit breaker armature, closing the main contact points and opening the telltale contacts, causing the light to go out.

If the lamp bulb does not light when the ignition is turned on, ground the telltale terminal *to the engine* (not to another regulator terminal). If the bulb still does not light, check for loose connections or a burned out telltale bulb. If the lamp lights when the telltale terminal is grounded, the main circuit breaker contacts are probably fused (stuck closed) or the armature coil spring is weak or broken.

Delco-Remy System

In this system the generator telltale light is connected in a circuit with the battery and generator. When the generator begins to charge, the voltage build-up in the circuit opposes the battery voltage to the telltale light. As the differential between these two voltages decreases, the light goes out.

If the light stays on after the engine is started and running a little above idling speed, the generator should be checked.

If the light does not go on when the ignition switch is turned on before the engine is started, the telltale bulb should be checked. If the bulb is OK, check the entire telltale circuit for loose connections or for an open circuit.

SPEEDOMETERS

The following material covers only that service on speedometers which is feasible to perform by the average service man. Repairs on the units themselves are not included as they require special tools and extreme care when making repairs and adjustments and only an experienced speedometer mechanic should attempt such servicing.

The speedometer has two main parts —the indicating head and the speedometer drive cable. When the speedometer fails to indicate speed or mileage, the cable or cable housing is probably broken.

Speedometer Cable

Most cables are broken due to lack of lubrication, or a sharp bend or kink in the housing.

A cable might break because the speedometer head mechanism binds. If such is the case, the speedometer head should be repaired or replaced before a new cable or housing is installed.

A "jumpy" pointer condition, together with a sort of scraping noise, is due, in most instances, to a dry or kinked speedometer cable. The kinked cable rubs on the housing and winds up, slowing down the pointer. The cable then unwinds and the pointer "jumps."

To check for kinks, remove the cable, lay it on a flat surface and twist one end with the fingers. If it turns over smoothly the cable is not kinked. But if part of the cable flops over as it is twisted, the cable is kinked and should be replaced.

Lubrication

The speedometer cable should be lubricated with special cable lubricant every 10,000 miles. At the same time, put a few drops of the lubricant on the wick in the speedometer head.

Fill the ferrule on the upper end of the housing with the cable lubricant. Insert the cable in the housing, starting

at the upper end. Turn the cable around carefully while feeding it into the housing. Repeat filling the ferrule except for the last six inches of cable. Too much lubricant at this point may cause the lubricant to work into the indicating head.

Installing Cable

During installation, if the cable sticks when inserted in the housing and will not go through, the housing is damaged inside or kinked. Be sure to check the housing from one end to the other. Straighten any sharp bends by relocating clamps or elbows. Replace housing if it is badly kinked or broken. Position the cable and housing so that they lead into the head as straight as possible.

Check the new cable for kinks before installing it. Use wide, sweeping, gradual curves where the cable comes out of the transmission and connects to the head so the cable will not be damaged during its installation.

Arrange the housing so it does not lean against the cylinder head because heat from the engine may dry out the lubricant.

If inspection indicates that the cable and housing are in good condition, yet pointer action is erratic, check the speedometer head for possible binding.

The speedometer drive pinion should also be checked. If the pinion is dry or its teeth are stripped, the speedometer may not register properly.

The transmission mainshaft nut must be tight or the speedometer drive gear may slip on the mainshaft and cause slow speed readings.

FUEL PUMPS

Fig. 1 illustrates a schematic drawing of a typical fuel system in which a combination fuel and vacuum pump is incorporated. Figs. 2 and 3 illustrate two typical diaphragm fuel pumps. Fig. 4 differs in that the pump has a vacuum booster section. The booster section has nothing to do with the fuel system except that it is operated by the pump arm.

Fig. 1 Diagram of fuel system in operation

Fuel Pump Operation

During the first or suction stroke, the rotation of the eccentric on the camshaft operates the pump operating arm which pulls the lever and diaphragm downward against the pressure of the diaphragm spring, producing a suction in the pump chamber. The suction holds the outlet valve closed and pulls the inlet valve open, making the fuel flow from the supply tank through the inlet up through the filter screen and down through the inlet valve into the pump chamber. During the return stroke, the diaphragm is forced up by the diaphragm spring, the inlet valve closes and the outlet valve is forced open, allowing the fuel to flow through the outlet to the carburetor.

Vacuum Section Operation

The vacuum section of combination pumps operates the windshield wipers at almost constant speed. The rotation of the camshaft eccentric in this type pump also operates the vacuum booster section by actuating the pump arm which pushes a link and bellows diaphragm downward, expelling air in the vacuum chamber through its exhaust valve out into the intake manifold of the engine. On the return stroke of the pump arm, the diaphragm is moved upward, producing a suction in the vacuum chamber. This suction operates the vacuum section and draws air through the inlet passage from the windshield wiper.

Fuel Pump Performance

It is essential that the fuel pump deliver sufficient fuel to supply the requirements of the engine under all operating conditions and that it maintain sufficient pressure in the line between the pump and carburetor to keep the fuel from boiling and to prevent vapor lock.

Excessive fuel pump pressure holds the carburetor float needle valve off its seat, causing high gasoline level in the float chamber which in turn increases gasoline consumption.

The pump usually delivers a minimum of ten gallons of gasoline per hour at top engine speeds, under an operating pressure of from 2 to 6 psi (depending on the installation). The highest operating pressure will be attained at idling speed and the lowest at top speed.

Fuel Pump Tests

The fuel pump can be tested on the

Fig. 2 Fuel pump with built-in fuel filter

Fig. 3 Fuel pump with separate fuel filter

Fig. 4 Fuel pump with fuel filter and vacuum booster for windshield wiper operation

Fig. 6 Auto-Lite fuel pump

Fig. 5 Testing fuel pump pressure

Fig. 7 Carter fuel pump

car with a pressure gauge, a hose and a pint measuring can. With this equipment, it is possible to check the fuel pump to see if it is delivering the proper amount of gasoline at the correct pressure.

Pressure Test

To make the pressure test, disconnect the fuel pipe at the carburetor inlet and attach the pressure gauge and hose between the carburetor inlet and the disconnected fuel pipe, Fig. 5. Take the pressure reading with the engine running. The pressure should be within the limits permissible for the particular vehicle installation. The pressure should remain constant or return very slowly to zero when the engine is stopped.

Capacity Test

To make this test, connect the hose so the pump will deliver gasoline into the pint measure held at carburetor level. Run the engine at idle speed and note the time it takes to fill the measure. On the average it should take from 20 to 30 seconds, depending on the pump being tested.

When Pressure Is Low

Low pressure indicates extreme wear on one part, small wear on all parts, ruptured diaphragm, dirty valve or gummy valve seat.

Wear in the pump usually occurs at the rocker arm pivot pin and on the contacting surfaces of the rocker arm and links. Due to the leverage design, wear at these points is multiplied five times in the movement of the diaphragm. It is apparent, therefore, that very little wear will materially reduce the stroke of the diaphragm. The worn parts must be replaced for a satisfactory correction.

The diaphragm pull rod has an oil seal around it which prevents the hot oil vapors from the crankcase coming in contact with the diaphragm. If this seal is damaged, the oil vapors have a tendency to shorten the life of the diaphragm.

The first three conditions—extreme wear on one part, small wear on all parts and ruptured diaphragm—are brought

Fig. 8 A.C. combination pump with four vacuum valves and built-in fuel filter

Fig. 9 A.C. combination pump with four vacuum valves

about by usage, while dirty and/or poor fuel is usually the cause of valve trouble.

When Pressure Is High

High pressure is caused by a tight diaphragm, fuel between diaphragm layers, diaphragm spring too strong, pump link frozen to rocker arm.

A tight diaphragm will stretch slightly on the down stroke. As the pump operates, the diaphragm will rebound on the up stroke beyond its normal position, much as a stretched rubber band when it is suddenly released. This rebound will cause a higher than normal pressure in the pump chamber.

A loose diaphragm retainer nut or poor riveting on the diaphragm assembly may allow fuel to seep between the diaphragm layers. This will cause a bulge in the diaphragm and have the same effect as a diaphragm that is too tight.

A diaphragm spring that is too strong also causes a high pressure, for the diaphragm will operate longer before pressure of the fuel on the diaphragm will overcome the diaphragm spring.

On a combination pump there are times when the operating parts may become badly corroded and the links freeze to the rocker arm. In this condition the pump operates continually, resulting in a very high pressure and a flooding carburetor.

The remedy for all these conditions is to remove the pump for replacement or repair, using a repair kit.

When Capacity Is Low

A pump is extra efficient and will never starve the engine when it supplies fuel equal to or above the capacity of the pump. The pressure, of course, must be within specifications.

Low capacity is usually caused by an air leak at the intake pipe at these points: fuel pipe fitting at pump, bowl flange or diaphragm flange, fuel bowl. (It is assumed that the conditions of too little fuel have already been checked and the fuel pump is the cause of the difficulty.)

An air leak at the fuel pipe fittings indicate either poor installation of pump or a defective fitting. The fitting should be tightened or replaced.

A leak at the diaphragm flange may be caused by a warped cover casting, loose diaphragm cover screws or foreign material between cover casting and diaphragm.

A leak at the bowl flange of the cover casting can usually be corrected by the installation of an extra gasket. A warped top cover indicates that the pump must be replaced.

A chipped glass or bent metal bowl may cause a leak at the bowl flange as may a defective gasket or foreign material between gasket and bowl or cover casting. A chipped glass bowl must be replaced while a dented metal bowl can be straightened.

Vacuum Pump Troubles

To assist the manifold vacuum to operate the windshield wiper at a uniform rate under any engine load is the only function of the vacuum pump. Of course, "uniform rate" infers a wet windshield and not one covered with snow or ice. Failure to do the above indicates difficulty in either the vacuum system of the pump, windshield wiper motor, or tubes and connections.

Symptoms of trouble in the vacuum section show up in four ways: oil consumption, slow windshield wiper action, poor idle, noise.

In some cases it has been found that an engine which has given very good oil mileage suddenly appears to be using oil. Upon investigation, it will often be found that the vacuum booster has a ruptured diaphragm and is drawing oil fumes from the crankcase into the intake manifold. This can be checked by removing the cover of the vacuum section.

When the windshield wiper slows down excessively under engine load, it usually is an indication of a ruptured vacuum diaphragm or defective valve action in the vacuum pump. This condition may not be discovered immediately as the windshield wipers may not be used for long intervals.

Oil will be evidenced in the cover casting recesses if the diaphragm is ruptured. The pump should be removed and the diaphragm replaced.

On some vehicles the engine will idle very poorly when the vacuum diaphragm is ruptured. This is true when the tube from the vacuum pump is connected to one end of the intake manifold. The air leak through the vacuum section will give those cylinders on the end a lean mixture which results in a miss or poor idle. In many cases, this leads one to believe the valves of the engine are sticking; but if they are ground, the miss or poor idle remains.

This condition can be checked by removing the vacuum pump tube at the manifold and plugging the hole. If the miss or rough idle disappears, the trouble is an air leak through the pump or tube connections. The pump should be removed and repaired or the connections tightened to eliminate this trouble.

Sometimes a combination pump will give off a peculiar grunting sound on idle. In some cases this can be remedied by stuffing curled horse hair into the pump breather.

Vacuum Pump Test

With a combination fuel and vacuum pump the windshield wiper should operate at 80 to 100 strokes per minute through all ranges of car speed and load. The windshield should be wet when the test is made, otherwise the action will be slow.

Checking With Vacuum Gauge

To check the vacuum section, disconnect both inlet and outlet tubes and attach a vacuum gauge to the inlet (side that goes to windshield wiper). It is assumed that the engine, windshield wiper motor and blade, and connecting tubing have been checked and are in satisfactory condition.

Read the gauge when the engine is running at 1000 rpm (about 20 mph). It should read from 7 to 12 inches of vacuum on a normal pump. If the reading is less than 7, the pump should be removed and repaired or replaced. When making this test, the tube to the manifold should be plugged and the pump outlet should always be open or damage may result to the mechanism.

Checking Without Gauge

Disconnect the outlet tube (to manifold) from the pump and plug the end. Then operate the engine from idle through slow acceleration to about 40 mph. If the wiper starts operating at about 15 mph and reaches full speed at about 40 mph, the vacuum section is okay. If it does not operate, it may be the windshield wiper motor. This can be checked by connecting the intake manifold directly to the windshield wiper tube. Then slowly accelerate the engine from idle to about 25 mph. The wiper should operate at full speed. If it does not it can be assumed that the wiper motor or tubing is defective.

Fuel Pump Service

Illustrated are representative fuel pumps among the many models that have been produced. Before disassembling any pump, scribe a mark across the housings in such a manner that they may be reassembled with inlet and outlet fitting holes in correct location.

When disassembled, clean all parts (except diaphragms) in solvent and blow dry with compressed air. Examine the diaphragm for cracks, torn screw holes or ruptures. If deteriorated, install new diaphragm and pull rod assembly. Check the strainer screen and if found to be corroded or clogged, install a new screen.

Fig. 10 Auto Pulse electric fuel pump

Check the rocker arm for wear or scoring on that portion which contacts the camshaft eccentric. If arm is scored or worn, install a new one. When reassembling a pump, do not use shellac or other adhesive on a diaphragm.

AUTO PULSE ELECTRIC FUEL PUMP

This bellows type pump, Fig. 10, has a magnetic activating coil in the base with a drive spring through the center of the coil. A pressure screw is incorporated to increase or reduce the drive spring pressure to control output pressures. The armature and contacts are located above the coil. The drive spring presses against a vertical shaft to which the upper contacts and one-piece metal bellows are attached. The bellows, in addition to performing the pumping action, acts as a seal between the pumping chamber and the electric mechanism. The pumping chamber is above the electric mechanism and consists of an inlet and outlet valve through which the fuel flows. A screen is located in the top, or dome, of the pump.

Operation

On the intake stroke the coil is energized, extending the bellows and compressing the drive spring. The bellows then returns to its normal position in the pressure stroke, pushing fuel through the outlet valve. The contacts are open during this interval. At the end of the pressure stroke, the contacts close, energizing the coil and drawing the armature and bellows downward on the intake stroke. Electrical contact is made for only a short time during the intake stroke. This cycle is repeated as long as fuel is required.

Trouble Shooting

Disconnect the fuel line at the carburetor and turn on the ignition switch. If ample fuel flows, the pump is okay. If the pump races but fuel does not flow in sufficient volume, the cause is an air leak in the suction portion of the fuel line. If fuel does not flow at all, inspect the fuel lines for restrictions or check the electrical connections for a shorted or open circuit. If all is in order and the pump still does not operate, remove the pump and replace or repair as necessary.

Disassembly

1. Take off the filter bowl and screen.
2. Remove two screws attaching filter base to pump base.
3. The electrical unit of the pump may be exposed by removing he lower cover.
4. To separate the coil from the rest of pump, remove the pressure nut screw. Then use a ¼″ magneto wrench and loosen the drive screw nut below the bellows stud.
5. Insert a thin screwdriver into the coil hole and loosen the drive screw.
6. Remove the coil mounting screws.
7. Separate the coil from the armature by removing the armature mounting screws.
8. The bellows are removed by taking out the four bellows ring screws from the pump base.
9. Take out the bellows ring, bellows, gasket and air seal gasket.

Inspection

Wash the filter and bowl in solvent and blow dry with compressed air. The valves may be resurfaced with crocus cloth. Clean the faces of the pump base and bellows ring with a soft, dry cloth. Replace all defective electrical parts.

Assembly

Reverse the disassembly procedure to reassemble the pump, bearing in mind the following: Always use a new bellows when rebuilding this type pump. Make sure the inlet and outlet valves are not tight in their chambers. Use new gaskets throughout the assembly.

LPG CARBURETION

INTRODUCTION

LPG (liquid petroleum gas) is an ideal engine fuel similar to gasoline. Both are a product of crude oil but they differ in that LPG is more volatile; that is it wants to boil or become a vapor at ordinary atmospheric temperatures. When used in an internal combustion engine, LPG is converted from a liquid in the fuel tank to a dry gas before reaching the combustion chamber. By good carburetion and perfect mixing of dry gas with air, uniform distribution throughout the manifold is achieved. With gasoline, or wet fuel, this uniform mixture and distribution is not attained.

With complete burning at a rate slower than gasoline, LPG makes for smoothness of operation because of prolonged power impulses on the power stroke and more uniform bearing pressures.

Being a dry gas, crankcase dilution is minimized and likewise all ill effects such as thinning of the lubricating oil and washing the lubricating oil from the cylinder walls with resultant cylinder wear are eliminated. Lubricating oil can be safely used much longer than on gasoline due to the elimination of carbon deposits, dirt, acid, and water content in the lubricating oil.

Harmful carbon within the engine is eliminated. There is no exhaust smoke or obnoxious odors. The time interval between engine shut-downs for overhaul is prolonged. Rings, valves, cylinders, and all moving parts lubricated from the crankcase last longer, resulting in a very substantial reduction in cost of keeping equipment in operation.

DESCRIPTION

Butane and propane gases, captured at the refinery and liquefied by being put under pressure, are blended to a desired mixture and pumped as a liquid under pressure into specially constructed heavy steel tanks mounted on the truck. Tank pressures will vary from 20 to 175 psi (pounds per square inch) depending on the butane-propane mixture and atmospheric temperature. By reason of this tank pressure, no fuel pump is necessary. L. P. Gas tanks are never filled 100% full as 10% to 20% space must be allowed above the liquid for expansion.

Fig. 1 shows the flow diagram of the system.

Filtering

From the tank the liquid is piped to a liquid filter where scale from tank and fittings, and dirt or other solids are removed. From the filter, the L. P. Gas goes into the regulating unit. Final filtering is accomplished through a fine metal screen inserted in the fuel inlet connection of the regulator to further eliminate passage of undesirable foreign matter into the regulator.

Fig. 1 Fuel diagram of LPG (liquid petroleum gas) fuel system

Primary or High Pressure Regulation

Liquid butane is dropped from tank pressure (20-175 psi) down to a regulated 1 to 10 psi. By use of the oil-controlled pressure regulator, the pressure is maintained at 1 psi with engine stopped and 10 psi when engine is running.

Vaporization

This function is performed by the vaporizer coils heated by hot water circulated by the engine. The high pressure valve would freeze up under the rapid expansion of gases were it not for the application of heat. This is accomplished by taking hot water from the water manifold, directing it first around the expansion valve, then around the heating coils to vaporize the expanded fuel, then returning it to the intake side of the water pump.

In starting a cold engine, there is sufficient differential in temperature between the extremely cold expanding butane and the parts surrounding the valve to provide latent heat for initial vaporization. However, it is desirable, especially in cold weather, to take vapor from the supply tank for starting and engine warm-up.

Final Pressure Regulation

The final regulator in the regulating unit further reduces the pressure of the completely vaporized butane from its 1 to 10 psi to slightly below atmospheric pressure. This final or "metering" regulator is actuated by engine vacuum or "suction" by the intake stroke which opens the final fuel regulator sufficiently to allow enough fuel to pass along to the carburetor to run the engine according to throttle opening. It actually regulates the supply of gas and shuts off the supply when the engine is stopped.

Idling System

The final regulator also contains the idling system. Even though most fuel used for idling enters the carburetor through the main gas orifice, additional and supplemental fuel for idling is taken from the final regulator and by-passed to a point in the carburetor directly above the throttle disc. The idle adjustment is in this line. This source of idling fuel is independent of the main gas supply to the carburetor and is controlled by an entirely different system. The two sources combine to produce the correct idling mixture.

Carburetion

From the regulating unit, the L. P. Gas is piped to the carburetor for final mixing and proportioning of the fuel with air. The carburetor is closely related to the final regulator of the regulating unit and with the two in correct coordination, air-fuel ratios are automatically controlled for greatest power, economy and flexibility.

The carburetor has an "easy-starting" feature wherein by pulling the choke entirely shut, a separate air-gas mixing device is put into operation to produce a pre-determined starting mixture. A separate adjustment is provided on the carburetor for adjusting the starting mixture. When the choke is released, the starting device is rendered inoperative and the main carburetor air-fuel orifices come into play. Therefore, the choke must be entirely *closed* for starting and entirely *open* for running.

A fuel economizer, actuated by manifold vacuum, is also utilized to reduce fuel consumption when operating at less than 80% full power.

LPG SAFETY MEASURES

When Servicing Truck

1. To avoid accumulation of gas-air mixtures in and around a truck caused by undetected leaks, select a place where there is good air circulation.
2. Keep as far as possible from hot dip tanks, hot water cleaners, steam cleaners, welders or any device operating, with an open flame or which may produce sparks such as cutting, welding, grinding, chiseling or any such similar operation.
3. If the truck is placed over a pit or near one, a fan should be put in the pit for ventilation as the gas is heavier than air and can easily accumulate in a pit with no air circulation. Nearby open stairways, or elevator shafts leading to basements should be provided with air circulation to keep gas out, or basements should be ventilated.
4. Absolutely no smoking.

Preparing Truck for Service

1. Before taking the truck into the shop for service, exhaust all fuel from the system by shutting off the main valves at the fuel tanks and allowing the engine to run until it stops. Then turn off the ignition.
2. Before towing a disabled vehicle into the shop, shut the valve at the tank and bleed the fuel system of all fuel and gas.
3. Never bring a vehicle into the shop without first checking the fuel system and fuel tanks for leaks.

Before Starting Repairs

1. Remember that the fuel system is pressurized.
2. Make certain the tank valves are tightly closed and all fuel exhausted from the lines before starting any repair work on the fuel system.
3. Make certain there are no leaks before doing any repair work on any part of the vehicle.
4. Place a fire extinguisher close by so it can be quickly put to use.
5. It is advisable to place Danger and No Smoking signs on each side of the vehicle as well as warn other people who might wander into the shop.

When LPG Gets on Fire

LPG should be allowed to burn until, if possible, the source of fuel is shut off. A fire extinguished before this is accomplished can and may result in dangerous accumulations of gas which might result in a more serious flash or explosion.

When Servicing Fuel System

1. Replace worn or defective fittings.
2. Treat all threaded connections with an insoluble lubricant such as Permatex or aviation gasket maker.
3. Check entire system for leaks after connecting it up.
4. LPG is treated with rather an offensive strong compound or odorant as a warning agent to indicate even small quantities of gas leakage.

Checking For Leaks

1. Detection of the peculiar odor indicates a possible leak. If detected, do not turn on or off any lights or electrical switches on any device or vehicle. Immediately tow vehicle outdoors until leak is located and danger eliminated.
2. Frosting of connections indicates leakage at that point.
3. Normally there should be a slight film of frost on the hex headed plug and boss just above the inlet fuel line connection to the regulator.
4. Never use open flame to check for leakage.
5. Brush a lather of soap on with a soft brush which will indicate the presence of leaks.
6. All rubber hose regardless of length used anywhere in the fuel line or piping system should be very carefully inspected for loose connections or any sign of checking, cracking, etc. At the least sign of injury or deterioration replace immediately.

When Serviced and Checked for Leaks

1. Do not start engine first.
2. Raise hood and allow air to circulate around engine to drive out any possible accumulation of gas.
3. Check fuel in tank with rotary gauge located on tank to make sure fuel supply is available.
4. To start engine open vapor valve *slowly*.
5. Turn on ignition and start engine with choke fully closed and throttle ¼ open.
6. After engine starts open choke completely for normal operation.
7. Operate engine at fast idle until water temperature reaches 125°.
8. Turn *on* liquid valve.
9. Turn *off* vapor valve.

Important Dont's

1. LPG is not intended for any use other than to run the engine.
2. Do not use it as a substitute for solvents to clean parts, seats, cushions, trim, etc.
3. Do not use it in place of compressed air to inflate tires, blow out lines, or any other object or device which can be operated by air.
4. Do not perform any repair work on tanks. Have the necessary tank work performed by qualified firms who service such containers who are informed as to regulations, inspection and test after any repairs are made.
5. Never check fuel tanks without first shutting off engine.

MODEL 185F

Disassemble, Fig. 1

1. With transmission on bench or repair stand, remove hand brake assembly.
2. Disconnect flexible oil line from clutch release sleeve.
3. Remove clutch release pull back spring.
4. Remove clutch release bearing and sleeve assembly.
5. Remove clutch release levers and shaft.
6. Lock mainshaft by putting gears in two speeds and unscrew companion flange nut.
7. Use suitable puller to remove flange and brake drum.
8. Remove speedometer sleeve and driven gear.
9. Remove mainshaft rear bearing cover.
10. Remove speedometer drive gear.
11. Remove countershaft rear bearing cover.
12. With mainshaft still locked, remove countershaft rear bearing retainer.
13. Remove reverse idler gear shaft lock from rear of case.
14. Remove main drive gear bearing cap.
15. Pull main drive gear out through front of case.
16. Remove mainshaft pilot bearing from pocket of main drive gear.
17. Remove main drive gear bearing retaining nut and press off bearing.
18. Drive mainshaft back until rear bearing is clear of case.
19. Remove clutch hub from front of shaft.
20. Use suitable puller to remove rear bearing from mainshaft.
21. Tilt forward end of mainshaft upward and lift assembly through top of case.
22. Lift loose sliding gear from case.
23. Remove reverse idler gear shaft from rear of case and lift out gear.
24. Move countershaft assembly toward rear until rear bearing is free of case. Then pull off bearing.
25. Tilt forward end of countershaft upward and lift assembly from case. Remove front bearing spacer, which was freed by removal of assembly.
26. Remove countershaft front bearing from inside of case. Do not disturb snap ring and welch plug at front end of counterbore.
27. To remove drive and 3rd speed countershaft gears, remove snap ring and press off gears.
28. To disassemble mainshaft, fasten in vise with forward end up. Then remove snap ring, splined washer and 3rd speed gear, using care not to lose rollers. Remove bearing sleeve, lock pin, and locating washer.

NOTE—Do not remove bell housing from transmission case unless a new one is required. Assemble main drive gear and bearing cap in transmission case and tighten cap screws. Use bearing cap for centering bell housing and bolt housing in place.

Fig. 1 Clark 185F four speed transmission

Reassemble

Reassembly procedure is accomplished by reversing the order of disassembly. However, observe the following:

1. When installing drive and 3rd speed gears on countershaft, press them on shaft with long hubs of gears facing each other and install snap ring.
2. After installing countershaft assembly, check its operation to see that no binding or end play exists.
3. Install reverse idler gear with slot for shifter fork toward front of case.
4. To assemble mainshaft, place it in vise with forward end up. Then slide 3rd speed locating washer over shaft. Install bearing sleeve with lock pin in place toward front of shaft.
5. Install 3rd speed gear on mainshaft with internal teeth of hub upward. Apply grease to rollers and insert them between shaft and gear.
6. Place splined thrust washer over shaft and install new snap ring in shaft groove. It may be necessary to use a shim or two under snap ring due to matching tolerances.
7. Install clutch hub on mainshaft with small end of hub forward.
8. Place 1st and 2nd speed sliding gears in transmission with shift fork slot facing rear. Then tilt rear end of mainshaft downward and lower into transmission case and slide loose gears on shaft.
9. When installing main drive gear bearing cap, be sure to line up oil holes in cap with holes in case, after first seeing that holes are clean and open.
10. Mainshaft rear oil seal should be installed with open end facing in.
11. When installing clutch release bearing and sleeve, adjust clutch release fingers so that .003" clearance is pro-

Fig. 2 Clark 200 Series five speed transmissions

vided between sleeve and each finger or a total of .006" between sleeve and both fingers.

12. Install transmission cover by placing gears and shift forks in 2nd speed position.

200 SERIES

Disassemble, Fig. 2

1. Take off cover.
2. Remove hand brake assembly.
3. Lock mainshaft by placing gears in two positions at the same time. Then remove companion flange nut.
4. Remove brake drum.
5. Remove speedometer sleeve and driven gear.
6. Remove mainshaft rear bearing retainer; then remove speedometer drive gear.
7. Remove low and reverse rocker arm pivot bolt and take rocker arm from case.
8. Remove low and reverse fork bar through rear of case and lift out shifting fork.
9. Remove main drive gear bearing retainer cap.
10. Take main drive gear assembly out through front of case.
11. Slide direct and overdrive clutch hub forward and withdraw through front of case.
12. Remove mainshaft rear bearing snap ring. Then drive mainshaft back until rear bearing is free of case.
13. Pull rear bearing off mainshaft with suitable puller.
14. Tilt forward end of mainshaft upward and lift assembly out through top.
15. Remove countershaft rear bearing retainer.
16. Remove bearing retainer washer from rear of countershaft.
17. Remove countershaft rear bearing snap ring. Then move shaft back until rear bearing is out of case so it can be removed with a puller.
18. Tilt forward end of countershaft upward and remove. Then remove front bearing and spacer.
19. Remove reverse idler lock from rear of case.
20. Remove reverse idler gear shaft from rear of case, lift out gear and remove two roller bearings and spacer.
21. Remove sliding gears from mainshaft.
22. Hold splines of mainshaft in vise with soft jaws and spread snap ring, holding 4th speed (or overdrive) gear so it can be slid over splines and off end of shaft.
23. Turn forward steel thrust washer to align internal splines of washer with splineway on shaft and remove 4th speed (or overdrive) gear, bearing bushing, locating washer, 3rd speed roller bearing and gear, and locating washer, in that order.
24. Remove mainshaft pilot bearing.
25. To disassemble countershaft, remove front snap ring and press off gears.

Reassembly Notes

Reassembly of the transmission is accomplished in the reverse order in which it was disassembled. However, observe the following:

1. When assembling mainshaft, clamp it in a vise with front end up. Place 3rd speed gear rear thrust washer on shaft and slip on 3rd speed gear. Apply heavy grease to rollers to hold them in position and insert them between gear and shaft.
2. Place 4th speed (or overdrive) gear rear thrust washer in position. Slide bearing sleeve over shaft, being sure inner race locating pin is in position and engaging splineway in shaft. Place 4th speed (or overdrive) gear in position and then the front splined thrust washer, pushing it down so that a new snap ring can be installed.
3. Install 3rd speed sliding gear on mainshaft with internal teeth toward front end and install low and reverse sliding gear with slot for shifter fork toward front end of shaft. Install sliding clutch hub on mainshaft.
4. When installing main drive gear front bearing cap, place oil return hole at bottom to line up with hole in case. Be sure these holes are clear of any obstruction.

Fig. 3 Clark 230 Series four speed transmission

230 SERIES

Disassemble, Fig. 3

Shift the transmission into second speed and take off the cover and shifter assembly. Remove the speedometer driven gear. Disconnect the hand brake band and linkage from the transmission. Lock the transmission in two gears to prevent the mainshaft from turning and unscrew the nut from the rear of the mainshaft. Pull off the universal flange and brake drum.

Remove the bell housing and the main drive gear bearing retainer, then pull the gear assembly out through the front. Slip the sliding clutch gear off the mainshaft and withdraw it through the front. Disconnect the mainshaft rear bearing retainer and push the shaft to the rear far enough to permit the removal of the rear bearing and speedometer drive gear. Tilt the front end of the mainshaft upward and lift the assembly out through the top.

Take off the countershaft rear bearing cap and remove the two screws and washer from the rear bearing. Push the countershaft far enough to the rear to permit the rear bearing to be removed. Tilt the front end of the countershaft upward and lift the assembly out of the transmission case. Remove the lock, tap the reverse idler shaft out rearward and lift out the gear.

To disassemble the mainshaft, slip the sliding gear from the shaft. Remove the snap ring from the front of the third speed gear. Rotate the front thrust washer until its teeth align with the mainshaft splines and take off the gears, together with the roller bearings, inner race, and washers.

Fig. 4 Clark 250 Series Five Speed Synchronized Transmissions

To assemble, clamp the shaft in a vise with the front end up and slip on the second speed gear rear thrust washer. Assemble the second speed gear over the shaft and insert the rollers between the gear and the shaft, using grease to hold them in place. Install the third speed gear rear thrust washer and the inner race with the locating pin engaging mainshaft spline. Assemble the third speed gear over the race and insert the rollers, using grease to hold them in place. Slip on the front thrust washer and hold it down in order to install the snap ring. Lubricate the mainshaft splines and slip the sliding gear on the shaft with its internal teeth facing the front. Assemble the sliding clutch gear on the front of the shaft with the larger gear to the rear.

If necessary to disassemble the cover,

drive the expansion plugs out of the cover. With all rails in the neutral position, remove the set screws from the shift forks and push the rails out toward the front, holding a hand over the lock ball holes to prevent them from flying out. As each rail is removed, tag it to be sure that assembly is made correctly. Remove the expansion plug from the side of the cover and tilt the cover on its side to allow the interlock plungers to drop out. Disassemble the reverse shifter fork assembly.

Assemble in the reverse order after lubricating all balls, springs and interlock plungers. When assembling the reverse shifter lug plunger, be sure it works freely and turn the adjusting nut until the plunger is flush with the face of the slot for the end of the shift lever.

Assemble

Insert the reverse idler with the larger gear toward the rear and tap in the shaft. Assemble the countrshaft front bearing, its retainer and snap ring. Place the countershaft assembly in the case and install the rear bearing, the two retaining screws, washer and the retainer cap.

Position the mainshaft assembly in the case and replace the rear bearing, speedometer drive gear and rear bearing retainer. Lubricate the mainshaft pilot bearing, place it in position in the main drive gear and install the drive gear assembly through the front. Fasten the drive gear bearing retainer securely in position and replace the bell housing.

Complete the assembly by replacing the universal flange, brake drum, hand brake mechanism, transmission cover and speedometer driven gear.

250 SERIES

Five Speed Synchronized Units, Figs. 4 and 5

When assembling the transmission, use new snap rings, cotter pins, gaskets and oil seals. Lubricate each moving part as it is being assembled, and coat all bushings with a light film of petrolatum before installation.

Assembling Mainshaft

1. Clamp mainshaft in vise with front end up and install 3rd gear with internal teeth down and slip on thrust washer.
2. Place lock pin in 4th gear bushing (5th on O.D. units) and position bushing on shaft with lock pin toward upper end. Install gear on bushing with hub upward. Install thrust washer and snap ring.
3. Check end play of 4th gear. If not between .008-.012" replace thrust washer with one of a size that will provide correct end play. Thrust washers are available in four thicknesses ranging from .111" to .125".
4. Remove assembly from vise and install 2nd gear with internal teeth toward front. Install low-reverse gear with fork slot toward front.

Fig. 5 Clark 250 Series gearshift housing

Assemble Transmission

1. Install countershaft front bearing snap ring in case, then install new expansion plug in countershaft bore in case. Be sure to expand plug enough to prevent oil leakage.
2. Install countershaft front bearing in case. Install thrust washer on front end of shaft. Tip rear end of countershaft down and lower into case. Push shaft forward and insert it in front bearing.
3. Place rear bearing snap ring on bearing. Position bearing on countershaft with snap ring toward rear and install bearing on shaft.
4. Install reverse idler gear assembly in case with smaller gear toward rear of case. Drive reverse idler shaft into case until slot in shaft is flush with case. Install retainer in slot and secure with lock washer and bolt.
5. Tilt rear of mainshaft downward, inserting end of shaft through rear bore in case. Then lower front end of shaft until it is in line with pilot bearing opening and move assembly forward into position.
6. Place synchronizer on shaft with longer hub forward.
7. Install rear bearing on mainshaft with snap ring groove toward rear. Install snap ring on bearing and tap bearing onto mainshaft until snap ring is seated against case. Install speedometer drive gear spacer and gear on rear of shaft and pilot bearing on front end.
8. Install main drive gear and bearing in case. Tap front end of shaft with soft hammer until snap ring in bearing is seated against case. Position new gasket of proper thickness on case and install bearing retainer. Be sure that oil holes in retainer and gasket are aligned with hole in case.
9. Place countershaft rear bearing cap and gasket on case and install lock washers and bolts.
10. Install mainshaft rear bearing retainer with new seal and gasket.
11. Install 1st-reverse shift fork in case with fork engaged in sliding gear groove. Insert shift rail through hole in rear of case and through fork. Drive rail into case until edge of lock slot is flush with case. Install rail lock plate and secure with capscrew.
12. Place 1st-reverse rocker arm in case and install pivot bolt and nut.
13. Place new gasket on top of case and with gears in neutral, install gearshift housing, being sure shift forks engage slots in gears.
14. Install emergency brake and U-joint flange. Shift transmission into gear and tighten flange nut. If cotter pin holes do not line up, always tighten nut (not loosen) until cotter pin can be inserted.

260, 2600 & 300 SERIES

4 and 5 Speed Synchronized Units, Figs. 6 and 7

When assembling the transmission, use new snap rings, cotter pins, gaskets and oil seals. Lubricate each moving part as it is being assembled, and coat all bushings with a light film of petrolatum before installation.

Assembling Mainshaft

1. Clamp mainshaft in vise with soft jaws with front end up.
2. Position 2nd speed gear on mainshaft with internal teeth facing up.
3. Place 2nd gear retainer washer in position on shaft.
4. Install 2nd gear retaining ring in groove of shaft over locating ring.

Four Speed Models

1. Place 2nd speed synchronizer on mainshaft with counterbore in shift hub down.
2. Position synchronizer support over shaft above synchronizer and install locating washer.
3. With lock pin in place in fluted bushing, install fluted bushing on shaft with lock pin toward upper end. Tap bushing into place.

Fig. 6 Clark 260 and 300 Series four and five speed synchronized transmissions

4. Position 3rd speed gear on mainshaft with toothed hub up.
5. Install 3rd speed gear retaining washer on mainshaft, rotating gear so external teeth on washer mesh with internal teeth of gear.
6. Install snap ring on mainshaft, making sure it is securely locked in place.
7. Check end play on 3rd gear, which must be .004" to .012". Retaining washers of various thicknesses are available to obtain required end play.
8. Remove mainshaft from vise and install 3rd and 4th synchronizer assembly with lip on shift hub toward front.
9. Install 1st and reverse gear on shaft with fork slot toward front.

Five Speed Models

1. Referring to Figs. 6 and 8, place 2nd and 3rd speed synchronizer on mainshaft with counterbore in shift hub down.
2. Position 3rd speed gear on shaft with toothed hub down.
3. Install 3rd speed gear locating washer on shaft over 3rd speed gear.

4. With lock pin in place in fluted bushing, install fluted bushing on mainshaft with lock pin toward upper end. Tap bushing into position.
5. Position 4th speed gear on mainshaft with toothed hub up.
6. Install 4th speed gear retaining washer on splines of mainshaft, rotating gear to align external teeth of washer with internal teeth of gear so washer will drop into place.
7. Install snap ring on shaft so it is securely locked in groove. Check end play on 4th gear, which should be .005" to .012". Retaining washers are available in various thicknesses to obtain required end play.
8. Remove assembly from vise and install 4th and 5th speed synchronizer with lip on shift hub toward the front.
9. Install 1st and reverse speed gear with fork slot toward front.

Assemble Transmission

Note: If countershaft front bearing was previously removed and not reinstalled, install bearing as follows, using care not to damage the bearing during installation:

1. Using a suitable sleeve and an arbor press or hammer, press bearing in transmission case from clutch housing end of case. Open end of bearing goes toward rear of case.
2. Press bearing .007" below front face of case.
3. Tap rear end of countershaft down and lower into transmission case, running rear of countershaft through opening for bearing in rear of case far enough so front countershaft can be lowered into position. Push countershaft forward into position in front bearing.
4. Install countershaft rear bearing, being sure snap ring is in groove in outer race of bearing. Press bearing into place on shaft with snap ring toward rear. Press bearing into case until snap ring contacts case.
5. Install snap ring in groove in countershaft to retain bearing, being sure it is well seated in groove.
6. Insert one reverse idler bearing in reverse idler gear; then install bearing spacer and the second bearing in gear.
7. Install reverse idler gear in case with bevel on gear toward rear of case.
8. Insert reverse idler shaft through opening in rear of case and into idler gear. Make sure groove for retainer lock in rear of shaft is at bottom of shaft. Drive shaft in until inner edge of groove is flush with transmission case. Install retainer lock and lock screw.
9. Install mainshaft assembly in case by tilting rear end down and lowering into and through opening in rear of case, which is provided for rear bearing. Lower front end in line with pilot bearing opening. Move mainshaft forward into position, lifting assembly so 2nd gear will clear countershaft oil slinger.
10. Position mainshaft rear bearing over end of shaft with snap ring in outer race of bearing facing the rear.
11. Using a suitable sleeve and hammer, drive bearing on mainshaft and into case until snap ring on bearing contacts case.
12. Slide pilot bearing on front end of mainshaft.
13. Postion main drive gear and bearing into opening in front of case so that drive gear engages and meshes with countershaft gear and snap ring on bearing contacts case. It may be necessary to use a suitable sleeve and hammer to drive gear and bearing into position.
14. Install a new gasket on main drive gear bearing cap. Install bearing cap on case and tighten screws securely. *Oil return hole in bearing cap must line up with oil hole in transmission case.*
15. Install countershaft rear bearing cap and new gasket.
16. Install spacer washer and speedometer drive gear on mainshaft.
17. Install mainshaft rear bearing cap and oil seal and new gasket.
18. Install 2nd speed gear oil scraper to transmission case.
19. Install brake drum and flange.
20. Lock transmission in two speeds at once and install companion flange nut, torquing it to 250 ft. lbs. Then advance nut to nearest cotter pin hole and install cotter pin.
21. Install shift bar housing with new gasket, being sure forks engage slots and rings in gears.
22. Install control cover and new gasket on shift bar housing.
23. Make sure transmission is in neutral by holding brake drum and turning main drive gear.
24. Install speedometer driven gear and adapter, hand brake parts, P.T.O. covers, and clutch housing.

Fig. 7 Clark 260 and 300 Series gearshift housing

Fig. 8 Clark 260 and 300 Series five speed mainshaft assembly with fourth speed gear removed

270 & 290 SERIES

Five Speed Units, Fig. 9

When disassembled, wash all parts and inspect for wear, twisted shafts, galling, chipped gear teeth and other damage. Slight burrs can be removed by stoning. Install new gaskets, snap rings and shims. Replace all oil seals when unit is disassembled.

Fig. 9 Clark 270 and 290 Series five speed transmissions

Assemble Mainshaft

1. Clamp mainshaft in vise with front end up and place 2nd gear on shaft with oil catchers up. Slip 2nd gear washer on shaft. Install snap ring in groove over washer.
2. Install 2nd-3rd sliding gear on shaft. Place 3rd gear on shaft with toothed hub downward. Drop 4th gear locating washer on shaft. Then with lock pin in place in fluted bushing, install bushing on shaft with lock pin toward upper end.
3. Place 4th gear on shaft with toothed hub upward. Drop retaining washer on shaft. Then install snap ring on shaft so it is locked in groove.
4. Remove assembly from vise and install sliding gears on shaft.

Assemble Transmission

1. Install countershaft front bearing. Position spacer on forward end of shaft. Tip rear end of countershaft down and lower into case. Run rear of countershaft through bearing opening in rear of case far enough so that front of shaft may be lowered into position. Push countershaft forward into position.
2. Install bearing on rear of countershaft with snap ring groove toward rear.
3. Install reverse idler gear assembly with chamfered teeth toward rear of case. Drive shaft in case until forward face of slot in shaft is flush with rear of case and slot is lined up to permit installation of lock plate. Secure lock plate with capscrew and washer.
4. Tilt rear end of mainshaft assembly down and lower it into and through opening in rear of case. Lower front end in line with pilot bearing opening and move assembly forward into position.
5. Assemble rear bearing over end of mainshaft with snap ring in outer race facing toward rear. Install pilot bearing on mainshaft.
6. Install main drive gear and bearing assembly and install bearing cap and gasket. Be sure oil hole in cap is lined up with oil hole in case, and be sure passage is open and clear.

Fig. 11 Clark 400 Series. Installing mainshaft second gear bushing sleeve

Fig. 12 Clark 400 Series. Selecting fourth gear variable thickness retaining washer

Clutch retainer bearing return spring clip should be installed under head of screw in assembly of bearing cap.

7. Lock gears in two speeds at same time. Install countershaft rear bearing retaining nut, draw it up tight and stake it in place. Install countershaft rear bearing cap and gasket.
8. Install speedometer gear on mainshaft. Then install rear bearing cap and gasket.
9. Install brake drum and companion flange. Draw flange nut up tight and lock wih cotter pin.
10. Assemble gearshift housing, being sure shift forks engage slots in gears.

400 SERIES

Five Speed Synchronized Units

Because of the increasingly higher engine speeds and extended periods of high gear operation, positive lubrication of the mainshaft is provided in this transmission in the form of a mainshaft pump that supplies mainshaft gear bushings and bearings with adequate oil at all times.

The pump is composed of a rotor which surrounds and is driven by the input shaft, a single free-floating vane confined in the rotor, and a stationary housing provided by the input shaft bearing cap which forms an eccentric bore for the single vane to contact.

Assemble Subassemblies

When assembling the transmission, use new snap rings, cotter pins, gaskets and oil seals. Lubricate each moving part as it is being installed. Coat all bushings with a light coat of petrolatum before installation. Refer to Fig. 10.

Assemble Mainshaft

1. Clamp mainshaft in a soft-jawed vise with front end up.
2. Install mainshaft 2nd gear bushing sleeve and lock pin. Pin must be installed toward pilot end of mainshaft with oil hole in sleeve lined up with oil hole in shaft, Fig. 11.
3. To insure a proper tight stack-up between the 2nd gear bushing sleeve, selective retaining washer and snap ring, proceed as follows:
   a. Before 2nd gear is installed on bushing sleeve, place retaining washer on shaft and hold down securely on bushing sleeve.
   b. While holding snap ring parallel to retaining washer, slip snap ring into ring groove in mainshaft. Select variable thickness retaining washers until one is selected that will allow snap ring to fit securely in groove, Fig. 12.
   c. Remove selected washer and install 2nd gear and bushing over bushing sleeve.
   d. Place selected washer in position; then install snap ring into shaft groove. End play on 2nd gear must be .004″ to .010″.
4. Place 2nd and 3rd synchronizer with large end of hub toward rear on splines of mainshaft and drop into position. Install 3rd speed gear locating thrust washer on shaft.
5. Position 3rd gear and bushing over mainshaft with toothed hub down and drop into place.
6. Position 4th gear locating washer on shaft.
7. With lock pin in place in 4th gear bushing sleeve, install bushing sleeve on shaft with lock pin toward pilot or front end of shaft. It may be necessary to use a suitable sleeve and hammer to properly install sleeve. *Oil hole in sleeve must line up with oil hole in mainshaft.*
8. To insure proper stack-up between 4th gear locating washer, bushing sleeve, selective retainer washer and snap ring, follow the same procedure outlined for the 2nd gear parts.
9. Install 4th and 5th speed synchronizer with large end of hub toward rear.
10. Press pilot bearing on front end of mainshaft. Remove assembly from press and cover it with clean cloth until ready for installation.

Fig. 13 Clark 400 Series. Oil pressure rotor installed

Fig. 10 Clark 400 Series pressure lubricated five speed synchronized transmissions

Assemble Transmission

1. Install countershaft front bearing in bore of case, applying pressure on outer race of bearing only.
2. Place countershaft front bearing spacer in position on front end of countershaft.
3. Tip rear of countershaft down and lower assembly into transmission case, running rear end of countershaft through rear bearing opening in case far enough to permit front of countershaft to be lowered into place. Push countershaft forward into proper position.
4. Using hammer and suitable installer sleeve, install countershaft rear bearing. Install rear bearing retainer nut loosely.
5. Insert two roller bearings, separated by spacer, into hub of reverse idler gear.
6. Lower reverse idler gear into position in case. Gear with chamfered teeth goes toward rear of case.
7. Insert reverse idler shaft through rear of case, through reverse idler gear and into forward support boss. The shaft should be driven in until forward face of slot in shaft is flush with rear face of case and slot lined up to permit installation of locking plate.
8. Install reverse idler shaft lock on idler shaft, engaging lock with slot in shaft. Secure lock to shaft with cap screw.
9. Position mainshaft 1st gear and bushing and reverse gear in case.
10. Install mainshaft in case by tilting rear end of assembly down and lowering into and through reverse gear, 1st gear, and opening in rear of case. Lower front end of shaft in line with pilot bearing opening in case and move assembly forward in proper position.
11. Install pressure rotor backing plate on main drive gear.
12. Position pressure rotor drive pin on drive gear.
13. Install pressure rotor on drive gear, with side of rotor marked "Front" toward front of transmission away from backing plate. With rotor drive pin at top and vane slot of rotor at bottom, see that oil inlet hole in rotor is on left side of rotor vane slot, Fig. 13.
14. Position new O-ring seal in groove in pressure rotor backing plate.
15. Install bearing cap on main drive gear, aligning oil inlet and outlet holes between rotor backing plate and drive gear bearing cap. Align word "Top" on cap with "Top" on backing plate.
16. Position main drive gear, bearing cap, pressure rotor, and new gasket into case so the main drive gear engages and meshes with countershaft drive gear. *Oil inlet and outlet holes must line up with oil holes in transmission case and word "Top" on bearing cap toward top of case.* Install four cap screws and tighten securely.
17. Install mainshaft 1st gear thrust washer; then, using a suitable installer sleeve and hammer, install mainshaft rear bearing.
18. Lock transmission gears in two speeds at same time and tighten countershaft rear bearing nut. Draw nut up tight and stake in position.
19. Position speedometer gear on mainshaft.
20. If previously removed, install new mainshaft rear bearing cap oil seal, using a suitable sleeve and hammer. Lip of seal goes toward front of bearing cap.
21. Install mainshaft and countershaft rear bearing caps and new gaskets.
22. With transmission still "locked up", install hand brake companion flange and retainer nut.
23. Install speedometer driven gear and adapter, P.T.O. covers and drain plugs.

Fig. 3 Fuller Road Ranger eight speed transmission

ROAD RANGER

8 and 10 Speed Units

These transmissions combine a four- or five-speed main section with a two-speed auxiliary section at the rear to provide a total of eight or ten speeds forward and two reverse speeds. When equipped with an oil filter, as shown in Figs. 1 and 2, it is attached to either the right or left-hand power take-off opening. Fig. 3 illustrates the gear train of the eight-speed unit whereas Fig. 4 shows a cross section of the ten-speed unit.

LUBRICATION

These transmissions should always be filled through the auxiliary section filler plug opening. Openings between the front and rear sections allow the lubricant to seek its proper level in both sections. *Overfilling will slow the action of the auxiliary synchronizing clutches, Fig. 3, and the extra drag caused may result in damage to the synchronizer discs.*

TROUBLE SHOOTING

NOTE—Before removing the transmission from the truck for inspection, always check for possible trouble in the clutch, drive shaft, universal joints or rear axle.

Noisy Transmission

Excessive noise may be caused by misalignment due to loose mounting bolts, paint on the clutch housing or transmission faces, flywheel housing misalignment, loose parts, dirt or metal chips in the lubricant, or insufficient lubricant.

Transmission noise may also be caused by worn or damaged parts, which requires the removal of the transmission to replace worn parts.

Transmission Shifts Hard

Check the clutch pedal free travel adjustment and clutch parts. Inspect the transmission linkage for binding caused by bent or worn parts. Hard shifting may also be caused by improper lubricant in the transmission.

Transmission Jumps Out of Gear

Improper shifting may cause the transmission to jump out of gear. Be sure the gears are completely engaged before releasing the clutch pedal.

Check the transmission linkage adjustment and make necessary corrections. Check for excessive end play caused by wear in the shift forks, sliding

Fig. 1 Road Ranger eight-speed transmission (right side and rear view)

Fig. 2 Road Ranger eight-speed transmission (left side and front view)

Fig. 4 Road Ranger ten-speed transmission

gear fork grooves, thrust washers, output shaft or countershaft bearings, or clutch pilot bearing or bushing.

Inspect the detent springs in the gear shift housing and replace any that are broken or damaged. Check clutch housing alignment with the engine.

Oil Leakage

Oil leaks may be caused by overfilling the transmission or by using a lubricant that expands and foams while the truck is in operation.

Loose gear shift housing cover screws may allow the lubricant to escape between the housing and transmission case. Check the condition of the bearing retainers and gaskets. See that the transmission vent is open.

Bind in Air Cylinder or Connecting Linkage

With the auxiliary section in high range, relieve the pressure in the air system and disconnect the piston rod of the air cylinder. Slowly move the piston several times through the complete stroke cycle. If either bind or drag is evident, disassemble the cylinder to find the cause. When connecting the piston, check the entire linkage for bind resulting from misalignment.

Leak in Air Lines

Raise the air pressure in the lines to normal and coat all connections in the system with soapy water to locate leaks. Disassemble the leaky connections, coat them with sealing compound and reassemble. Replace worn, leaky air hose, and repair or replace connectors, lines and hoses which continue to leak.

Leak in Air Cylinder

With the air system at normal line pressure and shift lever in neutral, disconnect the hose at the air cylinder which is not under pressure. Check the open port in the cylinder for a leak past the piston leathers. If no leak is found, connect the hose.

Move the shift lever to neutral and move the range selector handle to its opposite position. At the air cylinder, disconnect the air hose which is *not* now under pressure. Check the open port for a leak past the piston leathers; if no leak is found, connect the hose.

Check for a leak at the seal in the cylinder cap where the piston rod enters the cylinder.

If the above procedures disclose a leak, disassemble the cylinder and check the leathers, barrel, seal and piston rod. Replace any defective parts.

Defective Air Valve

Disconnect air hoses at the cylinder and cap each hose securely. After raising the air pressure to normal, move the shift lever to neutral and raise and lower the range selector handle. With each movement of the handle a short, fast blast of air should be heard at the breather valve. If the air exhaust is not as described, the valve is defective and the "O" rings should be replaced.

With the gear shift lever in neutral and selector handle in low-range position, check the breather valve for an escape of air past the pressure (outside) "O" ring. Move the selector handle to the opposite position and recheck the breather valve for a leak past the pressure "O" ring.

With the engine not running and with normal line pressure, move the shift lever in a geared position and then move the range selector handle to its opposite position. With movement of the selector handle a short, fast blast or air should be heard at the breather valve. After the initial exhaust, check the breather valve for continued escape of air past the pre-exhaust (inside) "O" ring.

Move the shift lever to neutral to allow the air valve to complete the shift. Again move the shift lever to a geared position and move the selector handle to its opposite position. After the initial exhaust, check the breather valve for continued escape of air past the pre-exhaust "O" ring.

If a leak is found at the breather valve after either a complete range shift or pre-exhaust of the air valve, replace both "O" rings.

Block In Air System

Raise the air pressure to normal and move the shift lever to neutral. At the air cylinder, disconnect the hose which is not under pressure and move the range selector handle to its opposite position. If no air block exists, a loud, continuous air blast will escape from the disconnected hose. Move the range selector handle to its opposite position and reconnect the loose hose to the cylinder.

Move the range selector handle to its opposite position and proceed as above with the other hose. If this check reveals an air block, it can be located by inspection of the air valve and/or by inspection of the air lines.

Fig. 5 Selector handle adjustment

Fig. 6 Long and short shift cable connection

TRANSMISSION REMOVAL

The procedure for removing the transmission varies somewhat depending upon the truck in which it is used. In general, however, it is accomplished as follows:

1. Bleed air reservoirs.
2. Drain transmission.
3. Disconnect drive shaft.
4. Set parking brake and remove companion flange nut.
5. Remove parking brake assembly.
6. Disconnect speedometer cable at transmission.
7. Remove parking brake lever.
8. Move selector control cable to high range position and remove cable retaining clamps.
9. Disconnect cable at connector joint and remove cable and cable tube.
10. Remove gear shift lever housing.
11. Disconnect air line from air filter.
12. Disconnect air lines from air cylinder and remove cylinder from transmission.
13. Remove four lower transmission mounting bolts and install guide studs in the two lower holes.
14. Raise front axle on blocks and position jack under transmission.
15. Install safety chain.
16. Remove transmission support.
17. Remove two upper attaching bolts and remove transmission from truck.

TRANSMISSION INSTALL

Installation of the transmission is the reverse of the removal procedure. However, observe the following:

1. Torque the transmission-to-clutch housing bolts to 120-130 lbs. ft.
2. Torque the brake shoe support bolts to 180-220 lbs. ft.
3. Torque the companion flange nut to 275-350 lbs. ft.
4. Torque the gearshift housing attaching bolts to 35-40 lbs ft.
5. During installation of the selector cable, eliminate unnecessary bends, and do not bend the cable on a radius of less than 4 inches.
6. On tilt-cab models, route the connector end of the cable along the frame before attempting to adjust the cable. Position the frame clamps on the cable but do not attach the clamps to the frame.
7. Push the selector handle all the way down to the cable ring and shift the air valve into high range position.
8. Partially fill the cable tube with Lubriplate and slide it over the end of the long cable.
9. Attach the connector ends of the two cables and move the cable rearward into its bore in the valve housing.
10. Push the cable casing into the connector tube until it contacts the cable joint. *The selector handle must be held up in the high range position during this operation.*
11. With the cable casing in position against the joint, install the cable clamp and spacer on the adapter. *Tighten the bolts finger-tight.*
12. Position the control cable and clamps on the gear shift lever and tighten the clamp bolts securely. On tilt-cab models do not attach the clamps to the frame at this time.
13. Loosen bolts that attach cable clamp and spacer to adapter.
14. Push selector handle down until there is ⅛″ clearance between bottom of selector handle and cable ring, Fig. 5. *This clearance should not exceed ⅛″.*
15. Tighten cable clamp bolts to adapter 10-15 lbs. ft., being careful not to pinch cable casing.
16. Check operation of control cable, making certain that air valve shifts freely into both high and low range positions.
17. On tilt-cab models, install frame clamps.
18. Install transmission cover plate and close air reservoir valves.
19. Fill transmission with lubricant, start engine and check for air leaks.

AIR VALVE SERVICE

Removal

1. Remove floor mat and plate.
2. Move selector control cable to high range position and remove cable clamp and spacer from adapter.

Fig. 7 Air valve and plate

3. Disconnect long and short shift cables at connector joint, Fig. 6.
4. Disconnect 3 hoses at air valve and remove valve housing mounting bolts.
5. Remove air valve and plate, Fig. 7.
6. Remove Allen screw which holds adapter to gearshift housing and remove adapter.
7. Remove lockout spring and pin from bore in gearshift housing.

Disassembly

1. Remove 3 air line fittings from valve housing.
2. Remove breather valve, Fig. 8.
3. Remove Allen head pipe plug from center opening in side of valve housing.
4. *Remove short control cable only for replacement.* Remove Allen set screw from end of lower swivel and pull cable from swivel through opening in front end of valve housing, Fig. 8.
5. Remove upper and lower swivels and spring by prying outward at lower swivel. Spring tension will free both swivels as lower swivel clears side of housing.

Fig. 8 Air valve

6. Lift out slide bar, spacer and shift fork.
7. Remove welch plug from front end of housing by carefully forcing plug outward with small punch. *Inserts in housing must not be moved or damaged as plug is removed.*
8. Remove valve through welch plug opening by pushing with small screwdriver at shift fork slot.
9. Remove "O" rings from valve.

Inspection

1. Clean and inspect all parts, replacing as necessary.
2. Check tension of actuator and swivel springs, and examine the upper and lower swivels for wear or damage.
3. Check the slide bar, spacer and shift fork for wear or rust, and replace the 4 "O" rings if one or more show wear or damage.
4. Coat the slide bar, spacer, shift fork, lower swivel and contact points with Automatic Transmission Fluid.

Assemble

1. Install "O" rings on valve.
2. Position valve in housing with shift fork slot toward front of housing, and install welch plug.
3. Position slide bar, spacer and shift fork in housing. *Shift fork must engage groove in valve and spacer must be positioned between slide bar and shift fork, Fig. 8.*
4. If short cable was removed from lower swivel, pass new cable completely through swivel. Stake cable securely through set screw hole in swivel. Install set screw.
5. Push connector end of cable through its opening in front of valve housing.
6. Position upper swivel and spring guide and bracket in ends of spring, and position lower swivel in yoke of spring guide.
7. Compress spring until upper swivel enters its depression in slide bar and lower swivel rides on lower track in housing.
8. To provide maximum projection of cable, move slide bar to rear of housing.
9. Install Allen head pipe plug in center opening in side of housing.
10. Install breather valve and 3 air hose fittings.

Fig. 9 Removal of one screw from high-speed synchronizer clutch housing

Installation

1. Install lockout spring and pin in gearshift housing bore.
2. Position adapter and install retaining screw.
3. Position valve plate and air valve, install 4 mounting bolts and connect 3 hoses. Torque bolts to 10-15 lbs. ft.
4. Connect long and short shift cables and pull cable tube toward rear until it bottoms in valve housing.
5. Install cable retaining clamp and spacer on adapter and adjust cable as outlined under *Transmission, Install.*

AUXILIARY SECTION SERVICE

Separation Of Main And Auxiliary Transmissions

1. Disconnect 3 air hoses at air control valve and remove the 2 valves-to-cylinder hoses from transmission.
2. Remove air filter and air hose.
3. Remove air valve and plate from air valve adapter. *Do not lose small horseshoe spacer in air valve.*
4. With assembly shifted into neutral, remove main transmission gear shift housing assembly and auxiliary cover.
5. Remove auxiliary rear bearing cover and speedometer drive gear.
6. With a small punch, relieve the auxiliary countershaft rear bearing nut where it is staked to shaft. Shift main transmission into two gears and remove countershaft rear bearing nut. *This nut has a right-hand thread.*
7. Shift main transmission into neutral and auxiliary unit into low range. Remove lock wire from groove at front end of auxiliary high speed synchronizer clutch housing. Remove 3 set screws (in lock wire groove) which secure high speed synchronizer clutch housing to auxiliary drive gear, Fig. 9. Move clutch housing to rear against auxiliary shifting yoke.
8. Remove upper front nuts from two studs inside auxiliary case.
9. Remove 6 nuts retaining auxiliary case to main case.
10. Remove auxiliary case from main case by tapping with a soft mallet.

Disassemble

1. Remove auxiliary detent spring cap from boss under shift fork shaft, and remove spring and ball.
2. Remove shift lever fulcrum pin lock plate and withdraw pin, using a slide hammer.
3. Remove shift lever.
4. Remove swivel pin from shift shaft.
5. To remove shift fork, cut lock wire and remove shift fork lock screws. Withdraw shift shaft and remove fork and fork shoe.
6. Remove oil seal from shift shaft bore in rear of case.
7. Remove auxiliary output shaft pilot bearing.
8. Using a soft mallet, tap auxiliary output shaft forward out of rear bearing. Remove shaft by forcing it forward out of case through front bearing bore.
9. Remove low speed gear, high speed synchronizer clutch and low speed thrust washer from case.
10. Remove output shaft rear bearing from case by lightly tapping bearing outer race with soft drift.

Fig. 10 Auxiliary section output shaft

Fig. 11 Positioning synchronizer discs

11. To remove countershaft, tap shaft to rear until rear bearing is out of case. Remove rear bearing from shaft, using a suitable puller.
12. Tilt countershaft and remove it from top of case.
13. Remove front countershaft bearing by tapping lightly on outer race with a soft mallet. If countershaft drive gear is to be replaced, press it off the shaft.
14. To dismantle the output shaft assembly, Fig. 10, first remove the sliding clutch gear.
15. Press the output shaft 5/8" through low speed gear front thrust washer and bushing. *Pressing the shaft more than 5/8" will damage the small Woodruff key and thrust washer.* Move thrust washer forward against shoulder of shaft and press shaft through bushing until key is completely exposed. Remove key and press washer and bushing off shaft.
16. Disassembly of the two clutches is the same. At the rim of the clutch, remove the wire stop for the pressure plate retaining snap ring. Remove snap ring, pressure plate and discs from housing.

Inspection

Check the surfaces of all thrust washers. Washers scored and/or reduced in thickness should be replaced. Synchronizer discs scored, burned or warped should be replaced. Bearing covers grooved or showing wear from thrust of adjacent bearings should be replaced. Check oil return threads in bearing covers. If the sealing action of the threads has been destroyed by contact from the input and output shafts, replace the covers.

Assemble

1. Both synchronizer clutches are assembled the same way. Start with an inner disc (projections at inside diameter) and alternately place one inner and one outer disc in housing until 8 discs have been installed, Fig. 11.
2. Install pressure plate and snap ring. *Lock wire hole in rim of gear must be between open ends of snap ring.*
3. Install lock wire in housing rim and bend wire up internally and down externally. *Internal end must not extend above housing.*
4. Press countershaft drive gear on shaft, Fig. 12.
5. To assemble output shaft, refer to Fig. 10 and proceed as follows:
6. Install low speed gear front thrust washer on rear of shaft *with beveled edge toward front of shaft.*
7. Install Woodruff key and press low speed gear bushing onto shaft until thrust washer is firmly seated against spline shoulder.
8. Install new oil seal in shift shaft bore.
9. Position snap ring on countershaft front bearing and install bearing in case. Tap lightly with soft mallet if necessary.
10. Position countershaft front bearing thrust washer on countershaft and install it in case.
11. Position snap ring on countershaft rear bearing and install bearing, using a suitable bearing driver.
12. Place low speed gear and high speed clutch in case, making sure low gear teeth engage those of low countershaft gear.
13. Install output shaft through front of case, threading it through high speed clutch and low gear until low gear is fully seated on sleeve.
14. Position low gear rear thrust washer on output shaft *with beveled edge toward low gear.*
15. Install snap ring on output shaft rear bearing.
16. Block front of output shaft and install bearing in case, using suitable bearing driver.
17. Install sliding clutch on output shaft through front bearing bore with word "front" toward front end of shaft. Thread sliding clutch through both synchronizer clutches until it engages pocket in low gear. *Interference can be eliminated during installation of sliding clutch by turning synchronizer clutches until lugs on inside diameters line up with grooves in sliding clutch.*
18. Install shoe in shift fork. *Countersunk holes in fork must be up and rib in shoe must face the rear.*
19. Install shoe and fork in sliding clutch.
20. Insert shift shaft in case through fork. End of shaft with milled flats should be to rear. Make sure notches in shaft line up with holes in fork but do not install lock screws.
21. Shift sliding clutch into low speed position and install auxiliary detent spring, ball and cap. Torque cap to 25-35 lbs. ft.

Fig. 13 Reverse idler shaft and related parts

22. Install swivel pin on outer end of shift shaft.
23. Position shift lever on swivel pin. Insert fulcrum pin in case and through shift lever, lining up milled slot in pin with lock screw hole. Drive fulcrum pin into case until slot is flush with case.
24. Install fulcrum pin lock, capscrew and lockwasher, and torque to 20-25 lbs. ft.
25. Install shift fork lock screws and torque to 50-60 lbs. ft.
26. Install safety wires in shift fork screws.

Joining Main and Auxiliary Transmissions

1. Shift auxiliary section into low range. Move high speed clutch to rear against auxiliary shift fork.
2. Install auxiliary output shaft pilot bearing in bore of auxiliary drive gear.
3. Install new gasket between two transmission cases.
4. Attach main and auxiliary cases by fitting auxiliary section over gear which projects from end of mainshaft of main transmission. At the same time, fit auxiliary case over studs which project from rear of main case. The mainshaft rear bearing must be seated in shallow bore in rear of main case before two sections are joined.
5. Install retaining nuts holding two cases together and torque to 65-70 lbs. ft. *Do not overlook the nuts on*

Fig. 12 Auxiliary section countershaft and related parts

Fig. 14 Countershaft and related parts

the two upper studs on the inside of the auxiliary case.

6. Shift main transmission into two gears and torque auxiliary countershaft rear bearing nut to 250-300 lbs. ft. *This nut has a right-hand thread.* Stake nut at milled slots, and shift transmission into neutral.
7. Move high speed synchronizer clutch forward against auxiliary drive gear.
8. Line up three holes in outside diameter of high speed synchronizer housing with holes in projections on drive gear.
9. Fit high speed clutch on projections of drive gear and move it forward until flush against shoulder of gear, at the same time keeping holes in line.
10. Install three set screws which retain clutch to drive gear. Tighten screws securely and then back them off until the slots are parallel with lock wire grooves in synchronizer housing.
11. Install lock wire in groove at front end of synchronizer housing and through slotted heads of set screws.
12. Install speedometer drive gear.
13. Install auxiliary rear bearing cover with new gasket and torque bolts to 25-35 lbs. ft.
14. Install auxiliary transmission cover and gasket and torque bolts to 35-40 lbs. ft.
15. Shift gear shift housing in neutral and install with new gasket. Shift forks must enter grooves in mainshaft sliding gears and reverse shift lever must engage reverse shift gate. Torque gear shift housing bolts to 35-40 lbs. ft.
16. Install air filter.
17. Install air valve and plate on air valve adapter. Torque bolts to 10-15 lbs. ft. Make sure small horseshoe spacer is installed between slide bar and shift fork.
18. Connect air hose to front of air filter and top fitting of air valve.
19. Install two air cylinder hoses and clamps on transmission and connect hoses to air control valve.

4 SPEED MAIN SECTION

NOTE—Separate the main and auxiliary transmissions as outlined previously. Then disassemble the main section as follows:

Disassemble

1. Using a small punch, unstake countershaft rear bearing nut. Shift transmission into two gears and remove nut, *which has a right-hand thread.*
2. Remove input shaft bearing retainer and pull shaft and bearing out of front of case as an assembly.
3. If input shaft bearing is to be removed, unstake retaining nut and remove the nut, *which has a left-hand thread.* Shift transmission into neutral.
4. To remove mainshaft, shift reverse gear into mesh with countershaft, and shift sliding gear forward into second speed position. Then lift mainshaft from case.
5. Remove nut from reverse shift lever pivot pin on left side of transmission case. Force pin out of case and remove lever and pin.
6. Remove reverse idler shaft retainer through opening in rear of case.
7. Remove shaft by threading a capscrew into the shaft and use a slide hammer to pull shaft from case.
8. Remove splined reverse sleeve with reverse gear, bearings and spacer.
9. Remove reverse idler gear from sleeve.
10. Remove caged bearings and spacer from sleeve, Fig. 13.
11. To remove countershaft, pry it to rear until rear bearing is out of case.
12. Using a suitable bearing puller, remove bearing from countershaft.
13. Lift countershaft out of case.
14. To remove countershaft front bearing, rap front of case sharply with a mallet to jar bearing backward, and remove it from case.
15. To disassemble input shaft, remove bearing nut and press bearing from shaft.
16. If countershaft gears are to be removed, remove snap ring and press gears off shaft one at a time, Fig. 14. Remove Woodruff keys from shaft.

Fig. 15. Transmission mainshaft related parts

Mainshaft Disassemble

1. Secure mainshaft assembly in a soft-jawed vise.
2. Remove pilot bearing.
3. Tap sliding clutch off shaft.
4. At pilot end of shaft and between the splines, pry out third speed gear washer locking key. Remove washer and gear, Fig. 15.
5. Position mainshaft in a press, using sliding clutch gear as a base and press mainshaft 1/8" through third speed gear bushing and thrust washer. If a press is not available, pry bushing upward. *Travel of mainshaft is limited to 1/8" by the small Woodruff key installed under the sleeve. Pressing the shaft more than 1/8" will shear the key and damage the washer.*
6. Pry third gear bushing upward on shaft to expose Woodruff key, Fig. 16, and remove key.
7. Using weight of sliding clutch gear, jar second speed gear, third gear bushing and thrust washer off shaft.
8. Remove sliding gear.
9. Position mainshaft in press. Then press shaft out of first speed gear, sliding gear hub and second gear bushing.
10. Remove Woodruff keys from shaft and remove first gear thrust washer.
11. Unstake and remove mainshaft rear bearing nut, which has a left-hand thread.
12. Press rear bearing from mainshaft.

Mainshaft Assemble

1. Press mainshaft rear bearing on shaft with snap ring groove toward front and install snap ring.
2. Install rear bearing retaining nut and torque to 300-350 lbs. ft. Stake nut at slots milled into shaft.
3. Install first gear rear thrust washer with beveled edge on the I.D. toward rear of shaft.
4. Install first gear with clutching teeth toward front of shaft, Fig. 15.
5. Install large Woodruff key which prevents movement of sliding clutch gear hub.
6. Position sliding clutch gear hub on shaft with beveled edge at the I.D. toward rear of shaft. Line up keyway with key and press shaft through hub until hub is tight against shoulder of shaft. *When pressing shaft through hub hold first gear against its rear thrust washer.*
7. Install sliding clutch gear on its hub with fork slot to rear.
8. Install small Woodruff key which prevents movement of second gear bushing.
9. Position second gear bushing on shaft, making sure keyway is lined up with Woodruff key.
10. Press or tap bushing into position, making sure it fits tightly against hub.
11. Install second gear with clutching teeth toward rear.
12. Install third gear rear thrust washer with beveled edge at the I.D. to rear.
13. Install Woodruff key which prevents movement of third gear sleeve.

Fig. 16 Gaining access to third speed gear bushing key

14. Line up keyway in third gear bushing with the key, and press or tap bushing into position. Bushing must fit tightly against rear thrust washer.
15. Install third speed gear with internal clutching teeth toward front of shaft.
16. Install third gear retaining washer with beveled edge of lugs at the I. D. to rear. Turn washer in its groove until lugs are under splines on shaft. The thick end of this key must enter slot in washer. Check end clearance between third gear and its thrust washer, which must be .006" to .012". Adjust to specified clearance by selecting a third gear retaining washer of the proper thickness. These washers are available in thicknesses of .253-.255", .258-.260" and .263-.265".
17. Install sliding clutch with word "front" toward front of shaft.
18. Install mainshaft pilot bearing on mainshaft with roller retaining snap ring to rear of shaft.

Main Transmission Assemble

1. Install countershaft front bearing in its bore.
2. Lower countershaft into case and position front of shaft into front bearing.
3. Install countershaft rear bearing, using a suitable bearing driver.
4. Install countershaft rear bearing retaining nut finger-tight. This nut has a right-hand thread.
5. Install bearings and spacer in splined reverse gear sleeve, Fig. 13.
6. Install reverse gear in splined sleeve. Position gear and sleeve in case *with shift fork groove in gear toward front of transmission.*
7. Insert reverse idler shaft in case and through bearings and spacer. Line up slot in shaft with lock screw hole in case.
8. Drive shaft into case until front edge of milled slot in shaft is flush with case wall.
9. Install reverse idler shaft retainer and torque capscrew to 20-25 lbs. ft.
10. Install reverse shifting lug in bottom or gear end of reverse lever. Insert lug in lever from side opposite bosses. Install snap ring on grooved end of lug.
11. Position reverse shifting lever in case, and guide lug into groove in reverse sliding gear.
12. Line up hole in lever with hole in case and install pivot pin through lever and case. Install washer and nut on pivot pin and torque nut to 100-115 lbs. ft.
13. Shift reverse idler shaft into mesh with countershaft and move mainshaft sliding gear into mesh with second speed gear clutching teeth.
14. Lower mainshaft assembly into case, making sure all mainshaft and countershaft gears properly engage, and that the rear bearing is seated in its shallow bore in rear face of case.
15. Install input shaft, making sure mainshaft pilot bearing enters bore in input shaft. Block against rear of mainshaft as input shaft is installed.
16. Shift transmission into two gears and torque countershaft rear bearing nut to 225-275 lbs. ft. Stake nut in place.
17. If input shaft bearing was removed, install retaining nut and torque to 250-300 lbs. ft. Stake nut in place.
18. Shift transmission into neutral. Install input shaft bearing cover and gasket, making sure oil return hole in cover lines up with hole in case. Torque bolts to 25-35 lbs. ft.

5 SPEED MAIN SECTION

Service on the five-speed main section is quite similar to that described for the four-speed main section. However, due to the fact that the mainshaft has more parts and is, therefore, more complex than its four-speed counterpart, herewith is given the procedure for disassembling and assembling the five-speed unit mainshaft. For the balance of the assembly, refer to the procedures outlined for the four-speed unit.

Mainshaft Disassemble

1. With mainshaft assembly removed from case, mount assembly in a vise with soft jaws.
2. At pilot end of mainshaft and between splines, locate and pry washer retaining key from keyway.
3. Turn washer in its groove until lugs on the O.D. line up with spline grooves in shaft.
4. Remove upper bushed gear and front washer over pilot end of shaft.
5. Remove assembly from vise and jar pilot end of shaft against block placed on floor. The weight of third speed gear in Model R-95-C or second gear in Model R-950-C will jar sleeve and washer from shaft. Catch gear and clutch collar as they clear sleeve seat.
6. On Model R-95-C only, mount assembly in press, using rear face of second speed gear as a base. Press shaft through gear. This operation will also remove sleeve assembled in front of gear.

Fig. 17 Eight-speed transmission gearshift mechanism

7. On Model R-950-C only, mount shaft in press, using rear face of first speed gear as a base. Press shaft through gear and front sleeve. Using front face of overdrive gear as a base, press shaft and gear through gear and rear sleeve approximately ¾". *Travel of gear and sleeve is limited to ¾" by Woodruff key installed under sleeve; do not press shaft further.* Move mainshaft overdrive gear to its original position against shoulder on shaft. Using front face of sleeve as a base, press shaft through sleeve. Remove shaft from Woodruff key which prevents radial movement of sleeve. Then remove overdrive gear from shaft.

Mainshaft Assemble

1. Install all parts on mainshaft including sliding gears, bushed gears and rear thrust washers. *Install high speed sliding clutch with counterbore to rear. Install splined sleeve for sliding clutch collar with counterbore to front.*
2. On Model R-95-C only, over rear bearing seat and against first speed gear rear washer, install spacer approximately 1¾" to 2" long. Turn mainshaft rear bearing nut against spacer. Nut and spacer will hold sliding gear, rear bushed gear and washer in place as shaft assembly is placed in case.
3. Install mainshaft assembly in case. On Model R-95-C, remove spacer and nut mentioned above.
4. Install rear bearing, install and tighten nut securely, and stake nut in place.

GEARSHIFT MECHANISM

Fig. 17 shows a layout of the parts comprising the eight-speed transmission gearshift mechanism. A similar arrangement is used for the ten-speed unit.

Gearshift Housing Disassemble

1. Remove the air valve adapter plate and lock pin and spring from the bore in the air valve mounting surface.
2. Remove the welch plug from the interlock bore on the left side of the shift housing and, with air valve mounting face down, mount housing in a soft-jawed vise.
3. Make sure all shifter shafts are in neutral. Then remove lock wires and lock screws from shifting forks and gates, Fig. 17.
4. Remove welch plugs from rear of shift housing.
5. Remove shifter shafts, top one first, by driving them out front of housing. The detent springs and balls, interlock pin and balls, and intermediate air valve lockout pins must not be lost as shafts are removed. A detent spring and steel ball are depressed by each shaft and will be released from the bore as the shaft clears the hole in the rear hub.

Inspection

Shift forks and gates should be checked for wear. Check forks for alignment. Check lock screws in forks and gates. Replace parts showing wear or misalignment. Retighten and rewire lock screws. Check neutral notches in shafts for wear from interlock balls. Shafts indented at points adjacent to neutral notches should be replaced. Check spring tension on shift lever. Replace tension spring and washer if lever moves too freely. Check shift lever pivot pin and slot in lever for wear. Check auxiliary shift fork and shoe for wear. Replace if necessary.

Assemble

Reverse the order of disassembly to assemble the shift housing. Be sure the interlock pin is in the shaft. Torque shift gate and fork lock screws to 50-60 lbs. ft.

FIVE-SPEED UNITS

Figs. 18, 19, 20

Before dismantling a transmission, carefully clean the outside of the case to avoid the possibility of introducing dirt or other foreign material into the unit. This is important because dirt, being abrasive, is highly detrimental to highly polished parts such as bearings, sleeves and bushings. These, as well as other parts, should be cleaned as removed and protectively wrapped until ready for use.

In removing the control cover, do not force it off the transmission. Forcing may spring the yokes out of alignment and cause partial engagement or gear interference. Follow the directions relative to shifting and the cover can easily be removed. If binding occurs, a slight manipulation or movement to one side or the other will free it.

When disassembling the control cover, all parts should be laid on a clean bench in the same sequence as removed. This

procedure will not only simplify reassembling the yokes and bars in their proper places but will also reduce the possibility of omitting the small yoke bar interlock parts. If these parts are left out, the unit will shift into two speeds at the same time.

Unless absolutely necessary, the clutch housing should not be detached from the case. If it is detached, extreme care should be taken when reassembling the housing to maintain the alignment between its machined face and the mainshaft bores in the case; also the concentricity of the mainshaft bores and the flange pilot.

NOTE—The disassembly procedure which follows is based on the assumption that the transmission has been taken from the chassis and that all supplementary equipment such as universal joint companion flanges and brake assemblies have been removed.

Fig. 19 Fuller five speed transmission. Series 5-72, 720, 5-74

Control Cover, Disassemble

1. Shift transmission into 1st speed.
2. Remove hand brake lever.
3. Detach and lift off cover.
4. Place control lever in neutral.
5. Remove shift yoke lock screws.
6. Start with upper bar and drive shift bars from housing. Use care to see that none of the small yoke bar locking parts are lost as bars are removed.
7. To remove shift lever, take off rubber grip, and latch spoon if lever is equipped with latch rod.
8. Force dust cover up and off lever after removing lock screw from those so equipped.
9. Remove tension spring and washer from inside lever housing, and withdraw shift lever.

Fig. 18 Fuller five speed transmission. Series 5-33, 330, 5-43, 430

Mainshaft, Disassemble

1. Remove rear bearing covers from mainshaft and countershaft.
2. Lock gears and remove bearing lock nut from end of countershaft.
3. Pull mainshaft and countershaft assemblies to the rear.
4. Remove mainshaft rear bearing.
5. Tilt mainshaft and remove through top of case, leaving sliding gears inside case.
6. Remove loose sliding gears from case.
7. To remove gears and sleeve from mainshaft, remove pilot bearing and sliding clutch, using the latter to free bearing.
8. Remove mainshaft gear retaining washer key.
9. Rotate mainshaft gear retaining washer until its inside lugs line up with grooves in shaft.
10. Remove mainshaft bushed gears, sleeve and washers, using the rear bushed gear to start the sleeves.

Main Drive Gear, Disassemble

1. Remove clutch release mechanism.
2. Remove drive gear bearing cover.
3. Withdraw gear.

Reverse Gears, Disassemble

1. Remove high speed reverse shifting bar and yoke from inside the case (Models 62, 620, 65, 650, 72, 720).
2. Withdraw shaft or shafts and remove gear or gears from case.

Countershaft, Disassemble

1. Remove countershaft rear bearing.
2. Tilt countershaft and remove through top of case.
3. To disassemble countershaft, remove gear retaining snap ring.
4. Press gears from shaft one at a time.

Fig. 20 Fuller five speed transmission. Series 5-62, 620, 5-65, 650

Reassembly Instructions

With the exception of a few specific points, the general instructions for reassembly are merely the reversal of those for disassembly. The exceptions are as follows and should be given careful attention.

Clearances

1. On mainshaft helical bushed gears, replace worn washers to assist in maintaining original fit.
2. Hold end play of both gears to a minimum of .006". Check with dial indicator or feeler gauge.
3. Replace bushings in gears having excessive radial clearance.

Assembling Bushed Gears

When assembling either new or rebushed gears on the mainshaft or counter shaft, be sure that they move freely after having been assembled in their proper places. Clean all mounting parts and coat with clean oil before replacing gears.

Installing Bushings in Mainshaft Helical Gears

1. Remove old bushing.
2. Clean bore of gear carefully and remove all burrs.
3. Lubricate outside diameter of bushing and inside diameter of gear.
4. Carefully press bushing fully into gear.
5. Face off any projecting end of bushing.
6. Drill oil holes in bushing through holes in gear, making sure all holes are open.
7. Remove all burrs resulting from drilling and break all sharp edges on ends of bushing.

Installing Bushings in Reverse & Countershaft Gears

1. Remove old bushing, clean bore of gear and remove all burrs.
2. Press bushing fully into gear.
3. Spin over the projecting ends of the bushing.
4. Open the ends of the oil grooves with a file.
5. Drill oil holes in bushing through holes in gear, making sure all holes are open.
6. Remove all ridges and burrs resulting from drilling and spinning operations.

U-Joint Flange

The mainshaft is held in its proper place by the universal joint companion flange. The omission of parts between the flange and bearing, or failure to pull the flange tightly into place will allow the mainshaft to move endwise with resutant damage to the pilot bearing, mainshaft and main drive gear.

Sliding Clutches

All sliding clutches should be assembled to the shaft with the counterbore toward the bushed gears. An exception is the sliding clutches in 43 and 430 series, which have no counterbore. They are marked, however, on one end with the word "front," and must be assembled with the marked end toward the front of the transmission.

Power Take-Off

When attaching a power take-off, be sure sufficient filler blocks and gaskets are used to prevent the gears from meshing too deeply. If the gears bottom, they will damage not only themselves but also the transmission case.

SERIES 10-1120

Separating Front & Gear Boxes, Fig. 21

1. Disconnect auxiliary control rod from shifting bar.
2. Detach front case from rear case and separate two units. Start rear section by rapping bulges on either side of case. Complete the separation by prying in the opening between the two cases.

Auxiliary Section, Disassemble

1. Shift unit into direct drive.
2. Remove flat top cover.
3. To disassemble drive gear, remove capscrews and withdraw drive gear, bearings and cover as a unit.
4. Force drive gear through front roller bearing to separate gear and cover.
5. Remove nut from drive gear (left-hand thread).
6. Jar bearing from drive gear.

Auxiliary Mainshaft, Remove

1. Remove rear bearing cover from case.
2. Turn shaft so that key under sliding clutch is uppermost.
3. Force pilot bearing and sliding clutch from shaft.
4. Remove key from its keyway.
5. Turn mainshaft gear washer radially in its grooves until lugs on washer line up with grooves in mainshaft.
6. Withdraw mainshaft, leaving bushed gear and splined washer inside of case.
7. Remove bearing and rear thrust washer.
8. Press sleeve from mainshaft.
9. Remove loose parts freed by removal of shaft.

Auxiliary Shifting Yoke & Bar, Remove

1. Remove screw from yoke.
2. Withdraw bar and lift yoke from case.
3. Remove pipe plug over bar and lift out spring and ball.

Auxiliary Countershaft, Remove

1. Lock countershaft so it can't turn.
2. Remove rear bearing retainer plate.
3. Remove snap ring from countershaft front bearing bore.
4. From the rear, force countershaft from its seat in rear bearing through gears and spacer and out through front of case. The bearing washer will be driven from front bearing bore as countershaft emerges.
5. Press countershaft from front roller bearing.

6. Remove bearing from rear bore of case.
7. Lift two gears and spacer from case.

Five-Speed Section, Disassemble

1. Shift transmission into 2nd speed.
2. Detach and remove shift lever housing.
3. Detach and remove shifting bar housing.

Overdrive Gearing, Remove

1. Remove lock screw from overdrive shifting yoke.
2. Drive overdrive yoke bar to rear and out of case.
3. Remove overdrive shifting yoke.
4. Unlock nut from mainshaft splines and remove from shaft.
5. Remove overdrive mainshaft gear and front thrust washer.
6. Remove countershaft sliding clutch.
7. Pry countershaft overdrive washer key from its keyway.
8. Turn countershaft gear retaining washer in its groove until its lugs line up with grooves in shaft.
9. Pull countershaft bushed gear to rear, which will also remove the washer.

Clutch Shaft & Drive Gear, Remove

1. Remove clutch release mechanism.
2. Remove drive gear bearing cover.
3. Remove drive gear and bearing.
4. Mount gear in vise and remove drive gear retaining nut (left-hand thread).
5. Jar or press bearing from gear.

Mainshaft Assembly, Remove

1. Remove countershaft front bearing cover.
2. Drive countershaft forward as far as possible (⅛").
3. Remove mainshaft pilot bearing and sliding clutch by driving against clutch with a soft bar.
4. Mark the four tapped holes in the rear bearing retainer which have no capscrews assembled into them.
5. Remove all ⅜" capscrews from rear bearing retainer.
6. Install four of the ⅜" capscrews in the marked holes and, using as a puller, evenly tighten them to pull the mainshaft rear bearing to the rear and from the shaft. If the bearing does not clear the shaft after the full length of the puller screws is utilized, rap the rear end of the shaft sharply to drive it through the bearing.
7. Attach a small "C" clamp to the 3rd speed gear. Attach a chain hoist or block and tackle to the "C" clamp and lift the mainshaft assembly from the case, leaving the sliding gear inside the case.
8. Remove bushed gear and sliding gear from case.

Mainshaft, Disassemble

1. Mount assembly in a vise and pry 3rd speed gear washer key from between splines.
2. Turn 3rd speed gear retaining washer in its groove until its lugs line up with grooves in shaft.
3. Withdraw washer and 3rd speed gear over pilot end of shaft.
4. Jar pilot end of mainshaft against a wood block until weight of 3rd speed gear moves sleeve and washer not more than ¼" to front.
5. Insert on shaft end between washer and sleeve a C-shaped spacer made from strap iron, making sure that keyway in sleeve falls under opening in spacer.
6. Jar pilot end of shaft until woodruff key is completely exposed between open end of C-shaped spacer. Use a second C-shaped spacer wider than the original to completely expose the key.
7. Remove woodruff key and jar sleeve, washer and 3rd speed gear completely off shaft, catching gear as it clears sleeve seat.

Fig. 21 Fuller ten speed transmission. Series 10-1120

Reverse Gearing, Remove & Disassemble

1. Remove reverse idler shaft lock.
2. Attach puller at opening in rear end of case and withdraw reverse idler gear shaft.
3. Lift both sections of reverse gearing from case.
4. Remove two roller bearings and spacer from gear sleeve.
5. Remove thrust washers and buttons from case.
6. Remove bushed reverse gear from idler assembly.
7. Remove snap ring from sleeve.
8. Press reverse idler gear driver from sleeve.

Countershaft, Remove & Disassemble

1. Remove front bearing retainer plate.
2. Install two ⅜" x 2" capscrews in tapped holes in front flange of countershaft front bearing housing.
3. Pull front bearing housing and bearings from shaft by evenly tightening the two "puller" screws.
4. Pull countershaft rear bearing, sleeve and washer to rear until bearing completely clears its seat on shaft.
5. Insert a C-shaped spacer on shaft between washer and sleeve, making sure keyway in sleeve falls between open ends of spacer.
6. Pull countershaft rear bearing backward until woodruff key is exposed between open ends of spacer.
7. Remove key and pull rear bearing, sleeve and washer from shaft.
8. Remove snap ring from front end of shaft.
9. Press drive gear from shaft.
10. Remove woodruff key and press remaining gears off *one at a time.*

Main Transmission, Assemble Reassembly Precautions

When reassembling mainshaft bushed gears, make sure they move freely. All parts should be carefully cleaned and lubricated. The end play of all helical gears should be held to a minimum of .006" and a maximum of .014". Check carefully with either a feeler gauge or a dial indicator. Of the two limits shown in connection with end play, the minimum of .006" is by far the more important. To go below this figure is to invite trouble. The bushed gears may freeze to the shaft or sleeve as a result of insufficient endwise clearance.

All bushed and sliding gears should be replaced on the mainshaft before it is reinstalled in the case. This is necessary because of the difficulty of threading the rear end of the mainshaft through the 1st and 2nd speed sliding gear and the bushed 1st speed gear. Hold these gears in their proper positions as the mainshaft assembly is reinstalled.

Countershaft, Assemble & Install

1. Press individual gears on shaft one at a time in their proper position.
2. Install gear retaining snap ring.
3. Lower assembly into case.
4. Install front bearing adapter.

5. Install rear bearing cup in adapter.
6. Holding countershaft as straight as possible, install rear bearing.
7. Install front bearing rear cone, spacer, front cone and cup in that order.
8. Install front bearing retaining plate.
9. Install front bearing cover.

Reverse Gearing, Assemble & Install

1. Install splined drive gear on sleeve with chamfered teeth to rear, and with snap ring on each side.
2. Clean and oil sleeve and install bushed gear so internal clutching teeth will engage external teeth of sleeve.
3. Clean and oil bearings and install in sleeve with spacer between bearings.
4. Install buttons in thrust washers.
5. Insert idler shaft in rear boss until it protrudes inside case about $\frac{3}{16}$". Install rear washer on shaft.
6. Using a short bar slightly smaller in diameter than idler shaft, insert it in front boss to hold front thrust washer in place.
7. Lower idler assembly in place, being careful not to dislodge washers.
8. Install idler shaft. *Be sure to remove bar tool.*
9. Install idler shaft lock.

Mainshaft, Assemble & Install

1. Mount mainshaft in vise with companion flange end down.
2. Clean and oil 2nd speed gear seat and install gear with clutch teeth to rear.
3. Install 3rd speed gear rear thrust washer.
4. Install woodruff key in mainshaft.
5. Install 3rd speed gear sleeve, making sure key in shaft lines up with keyway in shaft.
6. Clean and oil 3rd speed sleeve and install 3rd speed gear with clutch teeth to front.
7. Install 3rd speed gear splined thrust washer with flat machined surface toward gear.
8. Turn washer until its lugs line up with mainshaft splines.
9. Install key in keyway between splines.
10. Remove mainshaft from vise and install first and reverse speed sliding gear with chamfered teeth to rear.
11. Clean and oil first speed gear seat and install gear with clutch teeth to front.
12. Lower mainshaft in case.
13. Install first speed gear rear thrust washer.
14. Install rear bearing with combination bearing puller and retainer assembled to it.
15. Install bearing retainer capscrews and wire.

Clutch Shaft & Gear, Assemble & Install

1. Press gear into bearing.
2. Install and peen bearing retaining nut into milled notches of gear.
3. Install mainshaft 3rd and 4th speed sliding clutch with counterbore to rear.
4. Install mainshaft pilot bearing with snap ring to rear.
5. Install clutch shaft and drive gear.
6. Install front bearing cover.

Fig. 22 Fuller Series 3-65 auxiliary transmission

Overdrive Gear, Install

1. Install countershaft overdrive gear front thrust washer.
2. Install key in countershaft.
3. Install countershaft overdrive gear sleeve.
4. Clean and oil sleeve and install overdrive gear with clutch teeth to rear.
5. Install splined rear thrust washer in its groove until its lugs line up with countershaft splines.
6. Install countershaft washer retaining key.
7. Install countershaft overdrive sliding clutch.
8. Install mainshaft overdrive gear front washer.
9. Install mainshaft overdrive gear with long hub to rear.
10. Install overdrive gear retaining nut and peen into mainshaft splines.
11. Install overdrive yoke and yoke bar.

Shift Bar Housing, Install

1. Shift transmission into 2nd speed.
2. Shift bar housing into 2nd speed.
3. Install shift bar housing, making sure yokes enter slots of gears.
4. Install attaching screws and tighten evenly and securely.

Auxiliary Section, Assemble

Countershaft—Place countershaft gears and spacer in case with long gear hubs to rear. Thread countershaft through gears. Install front and rear bearings. Install countershaft front bearing washer and snap ring in case bore.

Yoke—Install shifting yoke with attaching capscrews to rear. Tighten and lace screws with wire.

Mainshaft—Press low speed gear sleeve on shaft. Do not press it all the way to washer groove. Place low speed gear in case. Thread mainshaft through low speed gear from rear, at the same time thread shaft through splined thrust washer and sliding clutch. Turn splined washer in its groove until ites lugs line up with mainshaft splines. Install key in mainshaft keyway. Install low speed gear rear thrust washer and rear bearing. Install mainshaft pilot bearing.

Main Drive Gear—Install drive gear in case bore. Install roller bearing in cover. Install snap ring in groove in cover. Install front bearing cover. Insert attaching screws and wire.

Final Assembly—Install countershaft rear bearing retaining plate. Install one-piece rear bearing cover. Install yoke bar, poppet ball and spring. Install auxiliary section cover. Install auxiliary section to front section and tighten attaching screws securely.

3-65 SERIES

Three Speed Auxiliary Units, Fig. 22

1. Shift transmission in neutral and take off cover.
2. Remove shifting bars, yokes, balls and springs. *There will be an upper and lower ½" poppet ball, plus one interlocking ball located between two shifting bars. Use care to see that the springs and balls are not lost as the bars are removed.*
3. Remove mainshaft rear bearing cover, and speedometer drive gear and washer from mainshaft.

4. Drive mainshaft to the rear from inside of case, forcing mainshaft rear bearing out of case. Remove rear bearing from shaft.
5. Remove low speed sliding clutch gear through mainshaft rear bearing bore and over universal end of mainshaft.
6. Tilt mainshaft assembly and remove through top of case.
7. Disassemble mainshaft.
8. Force countershaft assembly to rear until cup of countershaft rear bearing has been forced from case. Then move countershaft back through rear bore as far as it will go.
9. Remove main drive gear bearing cover attaching screws. Then force drive gear backward through bearings and cover into interior of case; then lift out through top.
10. Remove drive gear bearing cover, thus freeing drive gear bearing spacer.
11. Remove countershaft front bearing cover and front bearing cup. See that shims are not lost or damaged.
12. Tilt countershaft and remove through top of case. Press gears from shaft one at a time.

Countershaft, Reassemble

1. Insert Woodruff keys in countershaft.
2. For Models A, D, E, F, press overdrive, PTO gear and drive gear on countershaft in order named, pressing them on one at a time. For Models B and C, press on low speed gear, overdrive gear, PTO gear or spacer, and drive gear. For models G and H, press on intermediate gear, PTO gear or spacer and drive gear. *Shaft enters chamfered side of gear bores.*
3. Install gear retaining snap ring on front end of countershaft.
4. Mount bearing cones on each end of countershaft.

Main Drive Gear, Assemble and Install

1. Install countershaft into case with rear bearing protruding through rear countershaft bore in case.
2. Remove snap ring from main drive gear bearing.
3. Press drive gear bearing partly on drive gear shaft, *leaving approximately ½″ space between bearing and drive gear.*
4. Install drive gear from inside of case through case bore until bearing snap ring groove is clear of case. Install snap ring in bearing.
5. Complete installation of bearing on drive gear, closing up the ½″ space left previously. When in correct position, bearing will fit in proper place in case bore with inner race solid against drive gear shoulder.

Countershaft, Install

1. Install countershaft front bearing cup in case bore.
2. Move countershaft to front and insert assembled cone on countershaft front bearing into cup.
3. Install countershaft rear bearing cup in case.
4. Install countershaft rear bearing cover and tighten screws securely.
5. Install countershaft front bearing cover, adding or subtracting shims to give free running clearance of .003″ to .005″ end play. When proper end play has been obtained, remove rear bearing cover.

Mainshaft, Reassemble

1. Grip mainshaft in soft jaw vise with pilot end up.
2. Install rear low speed gear washer (waffle side facing up) on shaft. Install low speed gear sleeve on shaft.
3. Install low speed gear with internal clutching teeth facing rear of shaft.
4. Install overdrive gear rear thrust washer.
5. Install overdrive sleeve.
6. Install overdrive gear.
7. Install overdrive gear spline washer with flat thrust surface toward gear. Turn washer in its groove until lugs on its inside diameter line up with splines of mainshaft.
8. Install overdrive gear washer key in keyway between splines of mainshaft.
9. Install direct and overdrive sliding clutch with counterbore to rear.
10. Install mainshaft pilot bearing with roller retaining snap ring to rear.

Mainshaft, Install

1. Lower mainshaft into case, engaging helical gears of mainshaft with those of countershaft.
2. Enter pilot bore into drive gear bore.
3. Install low speed sliding clutch gear over end of shaft with chamfered teeth facing low speed gear.
4. Install mainshaft rear bearing.
5. Install speedometer gear washer with chamfered side in, and speedometer drive gear on shaft.
6. Install mainshaft rear bearing cover.
7. Install oil seal in rear bearing cover.
8. Install drive gear bearing cover, *leaving cover nuts loose to prevent damage to outer bearing during installation.*
9. Install drive gear spacer and outer bearing, making sure bearing is firmly seated.
10. Tighten drive gear bearing cover nuts.
11. Install oil seal in drive gear cover.

INDEX & LUBE CAPACITY

Model	Speeds	Oil, Pts.	Page
245, 275	5	12	135
420	4	5½	136
433, 434	4	10	137
540, 541	5	10	137
875, 895	5	8	140
5401, 2, 3, 4	5	10	137

SERIES 245, 275

Disassemble, Figs. 1, 2

1. Remove nut from output shaft.
2. Remove parking brake, universal joint spline flange and parking brake drum.
3. Remove gearshift housing.
4. Remove power take-off covers and gaskets.
5. Remove speedometer driven gear and bearing from output shaft bearing retainer.
6. Remove output shaft bearing retainer and slide speedometer drive gear and spacer from output shaft.
7. Remove input shaft bearing retainer and pull shaft and bearing out through front of case.
8. Slide synchronizer assembly off output shaft and lift shaft out of case.
9. Pull reverse idler gear shaft out of case and lift out gear.
10. Remove countershaft front bearing retainer, unfasten retainer washer and remove washer.
11. Remove bolts from countershaft rear bearing cap. Tap countershaft toward rear until bearing cap and bearing is forced out of case.
12. Lift out countershaft front bearing.

NEW PROCESS TRANSMISSIONS

Disassemble Sub-Assemblies

Input Shaft—Remove lock nut from end of shaft and remove bearing. Remove snap ring from shaft bore and remove output shaft pilot bearings. Remove snap ring from output shaft bearing.

Output Shaft—Slide low and reverse gear and 2nd speed gear from shaft. Remove snap ring and remove 4th and 5th gear synchronizer hub. Slide 4th speed gear (5th gear on overdrive units) and thrust washer from shaft. Remove bushing from gear and pin from bushing.

Slide off 3rd speed gear and thrust washer and remove bearing rollers from gear. Separate synchronizer parts and inspect for wear or damage. Reassemble with new parts as necessary.

Countershaft—Remove thrust washer from front end of countershaft. Press gear cluster off shaft and drive key from shaft slot.

Reverse Idler Gear — Remove thrust washer from bore of gear and remove bearing rollers and spacer.

Assemble Sub-Assemblies

Reverse Idler Gear—Install spacer in gear. Coat bearing rollers with grease and install 31 rollers in each end of gear. Install washer at each end of gear next to rollers.

Countershaft—Install spacer on shaft and key in slot. Press gear cluster on shaft until gear is seated against spacer.

Fig. 1 New Process five speed transmission. Series 245, 275

Position thrust washer on forward end of shaft.

Output Shaft—Coat 3rd speed gear rollers with lubricant and install rollers in bore of gear. Place thrust washer on shaft and slide gear on shaft with spur gear teeth toward rear.

Install lock pin in 4th speed gear bushing (5th speed gear on overdrive units). Place thrust washer on shaft and install bushing. Install gear on bushing with shorter teeth toward front.

Position clutch gear on shaft and install snap ring in shaft groove. Check 3rd speed gear end play. If not within .006-.008", replace snap ring with one of the proper thickness to give correct end play.

Position 2nd speed gear on shaft with shift fork groove toward rear. Install low and reverse gear on shaft with shift fork groove toward front of shaft. Assemble synchronizer as shown in Fig. 1.

Input Shaft—Install bearing on shaft. Install lock nut and tighten until bearing is firmly seated against gear shoulder. Install snap ring in shaft bearing groove.

Coat pilot bearing rollers with grease. and install in bore of input shaft. Secure bearings with snap ring.

Installation in Case

1. Install snap ring on countershaft front bearing and tap bearing into case.
2. Position countershaft in case and insert forward end in front bearing.
3. Tap countershaft rear bearing and cap into case and onto countershaft. Install bolts and lockwashers.
4. Install countershaft front bearing retaining washer and retainer.
5. Position reverse idler gear in case and tap idler shaft into case until notch in shaft is flush with rear face of case. Install shaft retainer.
6. Place output shaft in case and slip on synchronizer.
7. Install input shaft through front of case. Tap assembly into case until bearing snap ring is seated in recess in case. Install and tighten bearing retainer.
8. Position output shaft into pilot bearing, then install shims on rear of output shaft. Install snap ring on output shaft bearing and tap bearing into case bore until snap ring is seated against rear face of case. Install spacer and speedometer drive gear on output shaft.
9. Install output shaft bearing retainer and tighten securely.
10. Check end play of synchronizer. If not within .040-060", change shims at rear of output shaft until correct end play is obtained.
11. Install speedometer driven gear and bearing. Install power take-off covers.
12. Place gears in neutral and install gearshift housing, tightening bolts to 30-40 lb. ft. torque.
13. Slide parking brake drum onto output shaft and place band and lever on drum. Install bolts to case and torque them to 30-40 lb. ft.
14. Install parking brake band anchor spring and adjusting screw, then adjust brake.

SERIES 420

Disassemble, Fig. 3

1. Remove nut from companion yoke.
2. Remove hand brake linkage and band.
3. Pull off brake drum and companion yoke.
4. Remove transmission cover.
5. Remove rear bearing retainer and

seal assembly, and speedometer drive gear.

6. Remove main drive gear bearing retainer, gear and bearing.
7. Remove snap ring and pull rear bearing from case. Remove shim pack and tie shims together for reassembly.
8. Remove synchronizer snap ring and slide synchronizer gear forward. Then slide synchronizer from mainshaft.
9. Lift mainshaft assembly out of case through sliding gears. Then remove sliding gears from case.
10. Remove reverse idler shaft lock plate, pull out shaft and lift gear from case.
11. Remove rear countershaft bearing retainer and bearing. Then remove front countershaft retainer, cap screws and lock plate, and remove bearing.
12. Lift countershaft assembly from case.

Reassembly

Reverse Idler Gear—Install spacer in gear. Coat roller bearings with grease and install a complete set of 31 rollers in each end of the gear. Install a thrust washer in each end of the gear.

Countershaft—Install spacer and drive key in shaft keyway. Remove all burrs from key and shaft and press gear cluster onto shaft until gears bottom on spacer. Then install thrust washer on forward end of shaft.

Mainshaft—Coat third speed gear roller bearings with grease and place in third speed gear. Install thrust washer on mainshaft. Position third speed gear with spur teeth toward rear of shaft and slide gear on shaft.

Install lock pin in fourth speed gear (fifth on overdrive units). Place thrust washer on shaft and install bushing on shaft. Position fourth (or fifth) speed gear with shortest teeth toward front end of shaft. Install gear on bushing.

Install mainshaft synchronizer gear on mainshaft and secure with snap ring in shaft groove. Check snap ring for proper thickness by testing third speed gear end play. Snap rings are available in .002″ steps each to obtain desired end play of .006 to .008″.

Position second speed gear with shift fork groove toward rear of shaft and slide gear on shaft.

Main Drive Gear—Install bearing on shaft. Install lock nut and tighten securely to seat bearing against gear shoulder. Install snap ring in bearing groove. Lubricate mainshaft pilot bearing and place it in main drive gear bore.

Installation in Case

Countershaft—Install snap ring on countershaft front bearing and tap bearing into case. Lower countershaft in case and insert shaft into front bearing. Install new gasket on rear bearing retainer and tap rear bearing and retainer assembly into case and on countershaft. Install retainer cap screws and lock washers and tighten securely. Install countershaft front bearing lock plate and secure screws with lock wire. Install front bearing retainer, using a new gasket, and tighten securely.

Fig. 2 New Process 245 and 275 gearshift housing

Reverse Idler Gear—Place gear in position and tap shaft through case and gear until notch in shaft is flush with rear face of transmission case. Install shaft lock plate.

Mainshaft & Main Drive Gear—Place low and reverse gear in case. Lower mainshaft into case, passing it through low and reverse gear. Then insert shaft through rear of case far enough to install synchronizer parts one at a time on front end of shaft.

Insert main drive gear in case, tapping it with a soft hammer until the bearing snap ring is seated against case. Install main drive gear bearing retainer, using a new gasket, and tighten securely.

Place synchronizer outer stop ring on main drive gear and position front end of mainshaft into pilot bearing. Then install shim pack (as removed) on rear end of mainshaft.

Install snap ring on mainshaft rear bearing. Tap bearing into case until retainer seats against case. Install speedometer gear on mainshaft. Install mainshaft rear bearing retainer, using new gaskets, and tighten securely.

Install companion yoke and nut, tightening nut from 95-135 lbs. ft. torque. Check gears in neutral and in all speeds for free rotation.

Check synchronizer end play by placing feeler gauges diametrically opposite each other. End play should be .040 to .060″; if not within these limits, adjust by removing or adding shims at the rear of the case to obtain the desired result.

With gears in neutral, install a new gasket and install the transmission cover. Tighten cover screws to 30-40 lbs. ft. torque.

Install hand brake and fill transmission with correct amount of lubricant.

SERIES 433, 434, 540, 5400

Service Note

The four speed and five speed transmissions covered in this material are constructed basically in the same manner.

Fig. 3 New Process 420 Series four speed transmissions

The second speed gear and second speed synchronizer inner ring is removed from the mainshaft on five speed units and replaced by a spacer to make up the four speed transmissions.

Disassemble, Fig. 4

1. Remove nut from output shaft.
2. Remove parking brake, universal joint spline flange and parking brake drum.
3. Remove gearshift housing.
4. Remove power take-off covers and gaskets.
5. Remove speedometer driven gear and bearing from output shaft bearing retainer.
6. Remove output shaft bearing retainer and slide speedometer drive gear and spacer from output shaft.
7. Remove input shaft bearing retainer and pull shaft and bearing out through front of case.
8. Slide synchronizer assembly off output shaft and lift shaft out of case.
9. Pull reverse idler gear shaft out of case and lift out gear.
10. Remove countershaft front bearing retainer, unfasten retainer washer and remove washer.
11. Remove bolts from countershaft rear bearing cap. Tap countershaft toward rear of case until bearing cap and bearing is forced out of case.

Disassemble Sub-Assemblies

Clutch Shaft—Remove lock nut from end of shaft and remove bearing. Remove snap ring from shaft bore and remove output shaft pilot bearings. Remove snap ring from output shaft bearing.

Mainshaft—The following procedure applies to the five speed transmission. The four speed transmission is disassembled in a similar manner except name of parts will not agree with the following procedures.

Slide low and reverse gear and 2nd speed gear from shaft. Remove snap ring and remove 4th and 5th gear synchronizer hub. Slide 4th speed gear (5th gear on overdrive units) and thrust washer from shaft. Remove bushing from gear and lock pin from bushing.

Slide off 3rd speed gear and thrust washer and remove bearing rollers from gear. Separate synchronizer parts and inspect for wear or damage. Reassemble with new parts as necessary.

Countershaft — Remove thrust washer from front end of countershaft. Press gear cluster off shaft and drive key from shaft slot.

Reverse Idler Gear—Some models of these transmissions are equipped with a

Fig. 4 New Process 540 and 5400 Series five speed transmissions. Series 433 and 434 four speed transmissions are basically the same. In order to make up the four speed units, the second speed gear and second speed synchronizer inner ring are omitted from the mainshaft on five speed units and replaced by a spacer.

bushing type reverse idler gear, whereas others have roller bearing type gear. Remove thrust washers from bore of gear and remove bearing rollers and spacer (if equipped).

Assemble Sub-Assemblies

Reverse Idler Gear—If roller bearings are used, install spacer in gear. Coat bearing rollers with grease and install 31 rollers in each end of gear. Install washer at each end of gear next to rollers.

Countershaft — Install spacer on shaft and key in slot. Press gear cluster on shaft until gear is seated against spacer. Position thrust washer on forward end of shaft.

Mainshaft—The following procedure is for five speed transmissions although four speed units are similar (see Fig. 4). Coat 3rd speed gear rollers with lubricant and install rollers in bore of gear. Place thrust washer on shaft and slide gear on shaft with spur gear teeth toward rear.

Install lock pin in 4th speed gear bushing (5th speed gear on overdrive units). Place thrust washer on shaft and install bushing. Install gear on bushing with shorter teeth toward front.

Position clutch gear on shaft and install snap ring in shaft groove. Check 3rd speed gear end play. If not within .006-.008", replace snap ring with one of the proper thickness to give correct end play.

Position 2nd speed gear on shaft with shift fork groove toward rear. Install low and reverse gear on shaft with shift fork groove toward front of shaft. Assemble synchronizer as shown in Fig. 3.

Input Shaft — Install bearing on shaft. Install lock nut and tighten until bearing is firmly seated against gear shoulder. Install snap ring in shaft bearing groove.

Coat pilot bearing rollers with grease and install in bore of input shaft. Secure bearings with snap ring.

Installation in Case

1. Install snap ring on countershaft front bearing and tap bearing into case.

2. Position countershaft in case and insert forward end in front bearing.
3. Tap countershaft rear bearing and cap into case and onto countershaft. Install bolts and lockwashers.
4. Install countershaft front bearing retaining washer and retainer.
5. Position reverse idler gear in case and tap idler shaft into case until notch in shaft is flush with rear face of case. Install shaft retainer.
6. Place output shaft in case and slip on synchronizer.
7. Install input shaft through front of case. Tap assembly into case until bearing snap ring is seated in recess in case. Install and tighten bearing retainer.
8. Position output shaft into pilot bearing, then install shims on rear of output shaft. Install snap ring on output shaft bearing and tap bearing into case bore until snap ring is seated against rear face of case. Install spacer and speedometer drive gear on output shaft.
9. Install output shaft bearing retainer and tighten securely.
10. Check end play of synchronizer. If not within .040-.060", change shims at rear of output shaft until correct end play is obtained.
11. Install speedometer driven gear and bearing. Install power take-off covers.
12. Place gears in neutral and install gearshift housing, tightening bolts to 30-40 lb. ft. torque.
13. Slide parking brake drum onto output shaft and place band and lever on drum. Install bolts to case and torque them to 30-40 lb. ft.
14. Install parking brake band anchor spring and adjusting screw, then adjust brake.

SERIES 875, 895

Disassemble, Fig. 5

1. Drain transmission.
2. Remove hand brake band and drum.
3. Remove transmission control housing.
4. Remove mainshaft rear bearing retainer, noting the number of gaskets present.
5. Remove oil seal and speedometer drive gear.
6. Remove main drive gear bearing retainer, noting the number of gaskets used.
7. Remove main drive gear.
8. Tap mainshaft to rear until rear bearing is free of case.
9. Remove synchronizer.
10. Use puller to remove bearing from rear of mainshaft. Remove shims and note number used as they control floating clearance of synchronizer.
11. Lift mainshaft assembly from case.
12. Remove reverse idler gear shaft from rear of case and lift out reverse idler gear.

13. Remove front and rear countershaft bearing covers, and bearing retainer plate from end of countershaft.
14. Tap front end of countershaft toward rear of case until rear bearing is free of case. Then lift countershaft and gear assembly out of case.

Reassembly

1. Install reverse idler gear assembly in case before installing countershaft gear assembly. This will permit clearance for removal of pilot shaft used to assemble bearings in idler gear.
2. A wood pilot shaft or a discarded idler gear shaft cut to a length of five inches may be used to facilitate assembling bearings in reverse idler gear. Diameter of wood pilot shaft should be $1\frac{1}{16}$".
3. A bench assembly of the reverse idler gear and bearings should be made before installing in case. Position pilot shaft and long spacer in idler gear. Insert 31 needle bearings and short spacer between pilot shaft and idler gear. Insert 31 needle bearings and short spacer in same manner at opposite end of idler gear. Position gear and bearing assembly in case. Push shaft flush against pilot shaft, permitting pilot to be removed from gear. Remove pilot shaft from inside of case.
4. The mainshaft third speed gear bearing consists of 50 individual needle bearings. To assemble bearings, position thrust washer and third speed gear on mainshaft. Insert each needle bearing between gear and mainshaft.
5. Select a snap ring of correct thickness that will provide proper running clearance of mainshaft third speed gear. Snap rings are available in three thicknesses (.090", .093", .096") for this purpose.
6. Select a snap ring for securing the clutch gear that will hold the gear tight against the shoulder on mainshaft. Four thicknesses (.087", .090", .093", .096") are available for this purpose. To check for the thickness required temporarily install the synchronizer clutch gear on the mainshaft before installing the overdrive gear and third speed gear. Insert snap ring in groove on mainshaft and check the gear for tightness.
7. The main drive gear bearing lock nut should be tightened sufficiently to seat bearing against gear shoulder.
8. Like parts of the synchronizer assembly are interchangeable. Preassembling of this unit before installing on the mainshaft is not required since parts may be installed individually.
9. Check and replace all thrust washers showing signs of excessive wear.
10. The mainshaft front and rear bearing retainers fit or end play for their respective bearing is controlled by gaskets. Install bearing retainers and cap screw, check clearance between each retainer and case with a feeler gauge. Then select a gasket or gaskets about .005" thicker than the clearance between retainer and case. Remove retainer, install selected gasket or gaskets and retainer. This will give a satisfactory condition as to bearing end play and sealing of transmission.

3000, 4000 & 5000 SERIES

Five Speed Synchronized Type, Figs. 1 and 2

1. To disassemble, remove gearshift housing.
2. Remove brake drum, spline flange, brake shoe, mainshaft rear bearing retainer, speedometer drive gear and spacer.
3. Remove countershaft rear bearing retainer and nut.
4. Remove left side power take-off cover.
5. Use puller to remove reverse idler shaft.
6. With hard wood block against front side of second speed gear, drive mainshaft toward rear until rear bearing is free of case. Remove snap ring and bearing.
7. Slide first speed gear off as mainshaft is removed from case.
8. Remove input shaft from case.
9. Remove countershaft rear bearing.
10. Work countershaft toward rear until it clears front bearing and lift assembly out of case.
11. Remove countershaft front bearing retainer and tap bearing out of case.
12. Remove reverse idler gear.

Assemble Mainshaft

1. Place 2nd speed gear on output shaft with clutch teeth toward front.
2. Install two Woodruff keys in mainshaft. Then press 2nd-3rd synchronizer clutch gear on mainshaft.
3. Place 2nd-3rd speed synchronizer, 3rd gear and 3rd gear sleeve on mainshaft. Press sleeve onto shaft until it bottoms on synchronizer clutch gear. *Third speed gear slots must line up with Woodruff keys in mainshaft.*
4. Install snap ring at front of 3rd gear sleeve.
5. Install 4th gear, thrust washer and snap ring on mainshaft.
6. Install 4th-5th synchronizer.

Assemble Transmission

1. Tap countershaft front bearing into case. Install bearing retainer with new gasket. Line up oil holes in retainer, gasket and case, and tighten bolts to 50-55 ft. lbs.
2. Place assembled countershaft in case and start shaft into front bearing. Drive rear bearing onto shaft and into case.
3. Install reverse idler and power take-off cover.
4. Tap input shaft and bearing into case and install mainshaft pilot rollers.
5. Install input shaft retainer without gasket and tighten bolts to bottom retainer on bearing snap ring. Check clearance between retainer gasket surface and case. Use gaskets that will prevent oil leakage and any end play. Install retainer with oil hole in line with gasket and case holes and

Fig. 1 Spicer 3000, 4000 and 5000 Series five speed synchronized transmissions

tighten retainer bolts to 25-30 ft. lbs.

6. Install low-reverse gear on mainshaft and position assembly in case. Drive mainshaft bearing into position.
7. Install and tighten countershaft nut to 350-450 ft. lbs. Install bearing retainer and torque bolts to 60-70 ft. lbs.
8. Install new seal in mainshaft rear bearing retainer, tightening bolts to 65-75 ft. lbs.
9. Install brake shoe, spline flange and nut, tightening nut to 275-350 ft. lbs.
10. Shift gears into neutral and install gearshift housing, tightening bolts to 35-40 ft. lbs.

6000 SERIES

Five Speed Synchronized Type, Figs. 3 and 4

1. To disassemble, remove gearshift housing.
2. Remove brake drum, spline flange and brake shoe.
3. Remove rear bearing retainers from mainshaft and countershaft. Then remove speedometer drive gear and spacer from mainshaft.
4. Remove countershaft rear nut.
5. Remove reverse idler gear shaft.
6. Using a hard wood block against front side of 2nd speed gear, drive mainshaft toward rear until rear bearing clears case. Remove snap ring and bearing from shaft.
7. Slide low-reverse gear from shaft as mainshaft is removed from case. Remove pilot rollers from input shaft.
8. Remove input shaft from case.
9. Remove snap ring and bearing from rear of countershaft. Slide countershaft toward rear of case until shaft clears front bearing and lift assembly out of case.
10. Remove countershaft front bearing retainer and tap bearing out of case.

Assemble Mainshaft

1. Slide 2nd speed gear and synchronizer clutch gear onto shaft. Install clutch gear retaining snap ring.
2. Slide 2nd-3rd synchronizer onto shaft, and press on 3rd speed gear.
3. Install 4th speed gear sleeve and 4th gear. Position thrust washer and install snap ring. Slide 4th-5th speed synchronizer onto shaft. Then slip low-reverse sliding gear on shaft.

Assemble Transmission

1. Tap countershaft front bearing into case. Install retainer with new gasket, lining up oil holes in retainer, gasket and case. Torque retainer bolts to 25-35 ft. lbs.
2. Start assembled countershaft into front bearing. Drive rear bearing onto shaft and into case.
3. With bearings in reverse idler gear, install gear in case, lining up flat surface on rear end of idler shaft

with position of lock tang on countershaft rear bearing retainer. Drive shaft into position.

4. Position mainshaft assembly in case. With wood block at front end of shaft, drive rear bearing into place.
5. Insert pilot rollers into input shaft, holding rollers with Lubriplate. Last roller must be inserted endwise.
6. Install input shaft and bearing.
7. Lock transmission in two gears and install and tighten countershaft rear bearing nut to 350-450 ft. lbs.
8. Install countershaft rear bearing retainer.
9. Install new oil seal in mainshaft bearing retainer. Place speedometer gear and spacer on mainshaft. Install bearing retainer.
10. Install input shaft retainer without gasket and tighten bolts to bottom retainer on bearing snap ring. Check clearance between retainer gasket surface and case, which should be .010-015". Select gasket pack that will seal oil and also prevent end play at bearing snap ring.
11. Install input shaft retainer with oil hole in line with gasket and case holes and tighten bolts to 25-35 ft. lbs.
12. Install brake shoe assembly, tightening bolts to 180-220 ft. lbs.
13. Install U-joint flange and torque flange nut to 275-350 ft. lbs.
14. Install parking brake drum.
15. With transmission in neutral, install gearshift housing and tighten bolts to 35-40 ft. lbs.

Oil Pump

The oil pump (when used) is bolted to the inner side of the clutch housing. The pump is fitted with a non-adjustable pressure relief valve consisting of a ball and spring held in place by a pipe plug in the side of the oil pump housing.

When assembling the pump, press the drive gear on the shaft so that the distance from the front end of the shaft to the front side of the gear measures $\frac{17}{32}$". This dimension should be maintained to prevent excessive wear on the side of the gear.

Assemble the oil pump driving gear and shaft in the housing. Press the driven gear shaft in the housing and then on the shaft. Assemble the relief valve and spring and install the pipe plug. Position the housing gasket, being sure the oil holes in the case are not covered by the gasket. Fill the oil pump with gear oil and fasten the assembly in place, being sure the oil holes line up.

Fig. 2 Spicer 3000, 4000 and 5000 Series gearshift housing

5831 SERIES

Three Speed Auxiliary Type, Figs. 5 and 6

1. To disassemble, remove gearshift housing.
2. Remove input shaft U-joint yoke.
3. Remove flange and brake drum from output shaft.
4. Remove brake shoe assembly.
5. Remove rear mounting bracket.
6. Remove output shaft rear bearing retainer and remove speedometer gear from shaft.
7. Remove input shaft bearing retainer and bearing spacer.
8. Remove countershaft rear bearing cap and shims. Tie shims together for use at reassembly.
9. Tap underdrive gear toward rear until bearing clears case. Pull bearing from shaft. Remove underdrive sleeve and hub through rear bearing bore.
10. Tilt front of output shaft upward and slide it out of case.
11. Remove pilot rollers from input shaft. Remove snap ring and tap input shaft and bearing into case.
12. Drive countershaft toward rear until rear bearing cup is out of case. Remove countershaft front bearing cup from case.

Assembly Notes

After countershaft is assembled, measure clearance between rear bearing cap and case. Then select a shim or shims that will provide .001-.003" end play. When adjustment is satisfactory, torque bolts to 45-55 ft. lbs.

When assembling the output shaft, position direct and overdrive hub with face of hub stamped "X" toward front end of shaft. Install underdrive hub with face stamped "X" toward rear of shaft.

Assemble Transmission

1. With gears in neutral and new gasket on case, place gearshift housing on gasket with outer ends of shift rods toward front of transmission and each shift fork engaged in its proper groove, Fig. 6. Torque housing bolts to 45-50 ft. lbs.
2. Install transmission trunnion, making certain it does not bind on bearing retainer.
3. Install U-joint flange and yoke on input shaft and torque nut to 275-350 ft. lbs.
4. Install transmission mounting bracket and torque bolts to 40-45 ft. lbs.
5. Install brake shoe assembly and rear U-joint flange (and drum) and torque nut to 275-350 ft. lbs.

7231 SERIES

Three Speed Auxiliary Type, Figs. 7 to 10

1. Remove gearshift housing.
2. Remove input shaft yoke.
3. Remove trunnion from front bearing retainer.
4. Remove output shaft flange and brake drum, brake shoe and output shaft bearing retainer.
5. Remove countershaft rear bearing cap and shims. Tie shims together for use at reassembly.

Fig. 3 Spicer 6000 Series five speed synchronized transmission

Fig. 7 Series 7231 input shaft parts

6. Remove input shaft assembly.
7. Tap underdrive gear toward rear until rear bearing clears case. Pull bearing off shaft.
8. Remove underdrive sleeve and hub through rear bearing bore and remove output shaft.
9. Drive countershaft toward rear until rear bearing cup clears case. Slide countershaft toward rear and lift out assembly. Remove countershaft front bearing cup.

Assemble Transmission

1. Install countershaft front bearing

Fig. 6 Spicer 5831 Series gearshift housing

cup. Lower rear end of shaft into rear bearing bore and position shaft in case. Install rear bearing cup.

2. Position countershaft rear bearing cap without shims. Measure clearance between cap and case. Select shims that will provide .001-.003" end play, and tighten bolts.
3. Position output shaft in case and slide hub and underdrive sleeve onto shaft. With rear end of output shaft extended beyond rear of case, drive rear bearing onto shaft. Drive bearing on shaft until it firmly seats in bore.
4. Install new oil seal in output shaft bearing retainer. Install speedometer gear on shaft and install bearing retainer, tightening bolts to 45-50 ft. lbs.
5. Install input shaft and bearing retainer as a unit.
6. Install parking brake shoe and tighten bolts to 180-220 ft. lbs.
7. Install output shaft flange and tighten nut to 275-350 ft. lbs. If brake drum was removed, install it and tighten nuts to 70-75 ft. lbs.
8. Install trunnion but do not tighten bolt. Position input shaft yoke on shaft, install nut and torque to 275-350 ft. lbs.
9. Install gearshift housing.

8341, 8345 SERIES

Four Speed Auxiliary Type, Figs. 11 to 14

1. Remove gearshift housing.
2. Remove flange (and drum) from output shaft.
3. Remove input shaft U-joint flange and dust deflector.
4. Remove trunnion and front bearing retainer cap.
5. Remove lockwashers from retainer cap bolts and reinstall cap. Then after removing bolts from retainer, use puller to remove retainer and front bearing. Remove cap and tap bearing out of retainer.
6. Remove brake shoe, output shaft bearing retainer, speedometer drive gear and 1st speed gear spacer washer.

Fig. 4 Spicer 6000 Series gearshift housing

Fig. 8 Series 7231 output shaft parts

Fig. 9 Series 7231 countershaft parts

Fig. 5 Spicer 5831 Series three speed auxiliary transmission

7. After sliding input shaft as far forward as possible, tap output shaft forward to start shaft out of its bearing. Then slide output shaft and bearing rearward until there is clearance for a standard bearing puller. Pull bearing from shaft and remove 1st gear thrust washer.
8. Place two 1″ thick wood blocks between input shaft and 3rd-4th clutch gear. Press output shaft forward until clutch gear lock ring is exposed. Remove two machined halves and wood blocks.
9. Pull output shaft out through rear of case. Remove output shaft parts from case, noting that there are double rows of bearing rollers in 1st, 2nd and 4th speed gears.
10. Remove input shaft through top of case and pilot bearing from shaft. Remove sleeve and inner bearing race from shaft.
11. Remove countershaft front bearing retainer washer, bearing cap and gasket. Press countershaft toward rear until shaft is freed from front bearing and rear bearing is out of case. Remove bearing from shaft and front bearing from case.
12. Remove countershaft from case, front end first.

Assemble Transmission

1. Assemble and install countershaft in case, being sure oil drain hole in rear bearing cap is at bottom and torque bolts to 45-50 ft. lbs.
2. Assemble and install input shaft in case.
3. Assemble and install output shaft components in case. Then with two 1″ thick wood blocks between input shaft and 3rd-4th clutch gear, press output shaft forward until shaft lock ring groove is beyond 3rd-4th clutch gear. Remove wood blocks. Slide 3rd-4th clutch gear forward and make sure that both parts of lock ring will center inside counterbore of clutch gear. Pull output shaft rearward until components are drawn into position.
4. Install output shaft bearing with snap ring groove to rear. Install spacer washer and speedometer drive gear.
5. Install rear bearing retainer and torque bolts to 65-75 ft. lbs. Install brake shoe assembly, output shaft flange and drum and torque nut to 275-350 ft. lbs.
6. Install input shaft bearing retainer and gasket, tightening large bolts to 75-100 ft. lbs. and small ones 25-30 ft. lbs. Install front bearing in retainer. Install bearing cap and gasket. Torque bolts to 40-50 ft. lbs.
7. Install trunnion with finished surface toward front and torque bolt to 50-55 ft. lbs.
8. After positioning dust deflector, install input shaft flange, tightening nut to 275-350 ft. lbs.
9. After aligning shift forks with clutch sleeves, install shift cover and gasket and torque nuts and bolts to 45-50 ft. lbs.

SERIES 7751, 7851

Fig. 15

1. Remove transmission cover.
2. Remove universal flange.
3. Unfasten retainer cap from rear of transmission case and remove speedometer drive gear and rear bearing retainer.

Fig. 11 Spicer 8341 Series input shaft parts

Fig. 13 Spicer 8341 Series countershaft parts

Fig. 10 Spicer 7231 Series gearshift housing

4. Pull overdrive shift shaft out through rear and lift out fork.
5. Remove overdrive housing countershaft cover and unscrew lock bolts that retain overdrive gears to countershaft.
6. Reach into overdrive housing and remove bolts which fasten this housing to main case.
7. Pull overdrive housing and gears to rear and force rear bearing from mainshaft.
8. Push mainshaft to rear until intermediate bearing is free of case.
9. Tilt mainshaft and lift assembly out through top.
10. Remove bell housing and main drive gear bearing cap.
11. Unscrew nut from main drive gear shaft and push drive gear into case and lift it out.
12. Remove snap ring from front end of countershaft.
13. Push countershaft to rear until bearing is free of case, then lift countershaft out through top.
14. Push out reverse idler shaft and lift out gear.
15. To disassemble the mainshaft, slip off sliding gear and clutch sleeve. Unscrew clutch gear retaining nut and strip mainshaft, being careful not to lose any of the bearing rollers.
16. Reverse the above procedure to assemble the transmission.

Fig. 12 Spicer 8341 Series output shaft parts

Fig. 14 Spicer 8341 Series gearshift housing

Fig. 15 Spicer Series 7751, 7851 five speed transmissions

8000 SERIES, 4 SPEED

Disassemble, Fig. 16

1. Shift transmission into reverse gear, remove cover screws and lift off shift cover.
2. Remove nut and pull off companion flange.
3. Remove mainshaft rear bearing cap and take off speedometer drive gear, spacer and thrust washer.
4. Slide mainshaft to rear far enough to free rear bearing from case and use a suitable puller to remove bearing.
5. Remove clutch release yoke and shafts.
6. Remove cap screws from main drive gear bearing cap and, using a suitable puller, remove bearing cap and main drive gear.
7. Remove mainshaft pilot bearing from drive gear pocket.
8. Lift mainshaft assembly out of case by its front end.
9. Remove countershaft rear bearing cap and the bearing retainer washer from rear end of countershaft.
10. Pull reverse idler gear shaft out with a puller.
11. Remove reverse idler gear, sleeve and bearing assembly.
12. Move countershaft to rear far enough to free rear bearing from case. Then use puller to remove bearing.
13. Slide countershaft to rear until front bearing is out of case and lift out assembly.

Main Drive Gear, Disassemble

1. Remove snap ring from inside of bearing cap.
2. Place bearing cap in arbor press and push bearing and main drive gear out of bearing cap.
3. Remove nut and press bearing off main drive gear.

Mainshaft, Disassemble

1. Remove 3rd and 4th speed clutch collar.
2. Remove low speed gear, being careful not to lose any of the needle bearings.
3. Remove low and 2nd speed clutch gear.
4. Remove 3rd and 4th speed clutch gear snap ring.
5. Place mainshaft assembly in arbor press with rear end down and press mainshaft through gears. Use care to see that none of the needle bearings and 3rd speed gear lock balls are lost as they fall out.

Countershaft, Disassemble

1. Use puller to remove front bearing.
2. Remove countershaft drive gear snap ring.
3. Place assembly in arbor press and press countershaft through gears.

Mainshaft, Disassemble

1. Coat inside bore of low speed gear with heavy grease. Then place two rows of needle bearings (72 per row) on inside of low speed gear with spacer between rows.
2. Assemble needle bearings in 2nd and 3rd speed gears in same manner.
3. Place mainshaft in vise with rear end down.
4. Place 2nd speed gear on mainshaft with clutch teeth to rear.
5. Place 3rd speed gear sleeve on mainshaft with flanged end of sleeve toward rear. Line up two notches on inside of sleeve with mainshaft splines. Place two sleeve lock balls in notches of sleeve and press sleeve on mainshaft.
6. Place 3rd speed gear on mainshaft with clutch teeth to front.
7. Place 3rd and 4th speed clutch gear

on mainshaft with hub of gear toward front and press in place. Then lock assembly with a new snap ring.

8. Place 3rd and 4th speed clutch collar on clutch gear with longer hub to rear.
9. Take mainshaft from vise and place low and 2nd speed clutch gear with shift fork collar to rear.
10. Place low speed gear on mainshaft with clutch teeth to front.
11. Grease one side of low speed gear thrust washer and place its greased side against low speed gear.

Transmission, Assemble

Reassembly of the transmission is largely the reverse of the disassembly procedure. However, the following should be noted:

1. Place reverse idler gear and sleeve in case with shift fork collar to rear of case.
2. Make sure flat on rear end of reverse idler shaft is lined up so countershaft rear bearing cap will lock shaft in place.
3. Main drive gear bearing cap is marked "Top" and should be so installed.
4. Be sure mainshaft rear bearing cap and gasket are installed with oil drain holes lined up.

8000 SERIES, 5 SPEED

Disassemble, Fig. 17

1. Shift transmission into reverse.
2. After removing cap screws, lift cover and shift forks off transmission.
3. Remove nut and pull off companion flange.

Fig. 17 Spicer 8000 Series five speed. Some models have double row ball bearing at rear of mainshaft

4. Remove mainshaft rear bearing cap.
5. Remove speedometer drive gear or spacer from mainshaft.
6. Slide mainshaft to rear until rear bearing is free of case. Then use a suitable puller to remove bearing.
7. Remove overdrive gear lower shift fork guide shaft and remove shift fork.
8. Remove transmission rear end cover.
9. Remove overdrive gear and bearing spacer from mainshaft.
10. Remove nut from rear end of countershaft and use a suitable puller to remove overdrive sleeve.
11. Remove countershaft overdrive gear and shift collar.
12. Slide mainshaft toward rear to bring center roller bearing out of case far enough to get a puller or "C" clamp on the outside diameter of the bearing. Then tap rear end of mainshaft toward front which will move bearing off shaft.
13. Loosen bearing puller or "C" clamp and slide mainshaft back and get another hold on center mainshaft roller bearing and again tap mainshaft forward as far as possible.
14. Repeat this procedure until center roller bearing is out of case and off mainshaft.
15. Remove clutch release yoke and shafts.
16. Remove cap screws from main drive gear bearing cap and with a suitable puller remove cap and main drive gear out of case, using the two puller screw holes provided.
17. Remove main drive gear pilot bearing from mainshaft.
18. Tilt front end of mainshaft upward and lift assembly out of case.
19. Remove cap screws and take off countershaft rear bearing retainer and thrust washer.

Fig. 16 Spicer 8000 Series four speed transmissions

20. Place a suitable puller in threaded hole in reverse idler gear shaft and pull out shaft.
21. Remove reverse idler gear and sleeve and bearing assembly.
22. Move countershaft to the rear until rear bearing is out of case. Then use a puller to remove rear bearing.
23. Slide countershaft toward rear until front end is out of case. Then lift assembly out by its front end.

Main Drive Gear, Disassemble

1. Remove snap ring on inside of bearing cap.
2. Place bearing cap in press and push bearing and main drive gear out of cap.
3. Remove bearing nut and press bearing from main drive gear.

Mainshaft, Disassemble

1. Remove 3rd and 4th speed clutch collar.
2. Remove low speed gear and needle roller bearings, being careful not to lose any of the rollers.
3. Remove low and 2nd speed clutch gear.
4. Remove snap ring from front end of mainshaft and press gears off shaft. Use care to see that needle bearings and 3rd speed gear sleeve lock balls are not lost during the pressing operation.

Countershaft, Disassemble

1. Use puller to remove front bearing.
2. Remove countershaft drive gear snap ring.
3. Press off countershaft gears one at a time by placing gears on bed of press and pushing countershaft out of gears.

Mainshaft, Assemble

1. Coat inside bore of low speed gear with heavy grease.
2. Place two rows of needle bearings (72 per row) on inside of low speed gear with spacer between rows.
3. Assemble needle bearings in 2nd and 3rd speed gears in same manner.
4. Place mainshaft in vise with rear end down.
5. Place 2nd speed gear on mainshaft with clutch teeth to rear of shaft.
6. Place 3rd speed gear sleeve on shaft with flanged end toward rear. Line up the two notches on inside of sleeve with mainshaft spline and place two sleeve lock balls in notches of sleeve. Then press sleeve on mainshaft.
7. Place 3rd speed gear on mainshaft sleeve with clutch teeth to front.
8. Press 3rd and 4th speed clutch gear on mainshaft with its hub to front. Then install snap ring in front of clutch gear.
9. Place 3rd and 4th speed clutch collar on clutch gear with longer hub to rear.
10. Remove mainshaft from vise and place low and 2nd speed clutch gear on mainshaft with shift fork collar to rear.
11. Place low speed gear on rear of mainshaft with clutch teeth to front.
12. Grease one side of mainshaft low speed gear thrust washer and place on mainshaft with greased side against low gear.

Transmission, Assemble

Reassembly of the transmission is largely a matter of reversing the disassembly procedure. However, the following should be noted:

1. Shift fork collar of reverse idler gear should be to rear of case.
2. When installing reverse idler gear shaft, make sure flat on rear of shaft is lined up so countershaft rear bearing retainer will lock reverse idler shaft in place.
3. Mainshaft pilot bearing must be assembled on shaft with snap ring in outer race to rear.
4. Main drive gear bearing cap is marked "Top" and it should be so installed.
5. Make sure countershaft overdrive gear clutch collar is installed with hub of collar toward gear. Make sure collar is a free slide fit on spline hub of gear.
6. When installing overdrive shift fork and shaft, place shift fork guide shaft in hole provided in rear of case. Tap it through case and line up shift fork and tap shaft on through hole in center support in main case.

SERIES 5531

3 Speed Auxiliary

Disassemble, Fig. 18

1. Remove transmission cover.
2. Remove both propeller shaft flanges.
3. Remove front support from main drive gear bearing cap.
4. Remove countershaft rear bearing cap, noting number of shims under cap.
5. Remove mainshaft rear bearing cap and snap ring from bearing.
6. Use puller to remove rear bearing.
7. Remove mainshaft assembly from case.
8. Remove drive gear bearing cap, pulling bearing and washer with cap.
9. Lift drive gear from case.
10. Force countershaft toward rear to remove bearing cap from case.
11. Lift countershaft from case.

Disassemble Sub-Assemblies

1. Slide spacer and shims off main drive gear. Then use press or bearing puller to remove bearing from gear.
2. Remove oil seal from bearing cap and tip cap to allow washer and bearing to fall out.
3. If bearing cup requires replacing, drive out old cup and press new part squarely in until cup bottoms in counterbore.
4. To disassemble mainshaft, first mark shift sleeves and clutch gears so they may be assembled in the same position when rebuilding transmission. Remove shift sleeves from clutch gears.
5. Support mainshaft at low speed gear and remove clutch gear by pressing mainshaft out of gears.
6. Remove spacer lock from between splines and remove gear and spacer from shaft.
7. Press clutch gear off mainshaft.
8. The countershaft low speed gear is integral with the shaft, whereas the other three gears are retained by a snap ring and each gear located by a key. Mark each countershaft gear so correct position will be known when assembling.
9. If necessary to remove countershaft bearings, use puller which will apply pressure on bearing race.
10. Remove snap ring from front end of countershaft.
11. Support gears one at a time and with arbor press, press countershaft out of gears.

Sub-Assembly Build-Up

1. Drive countershaft keys in place and press gears on countershaft, using marks previously made before gears were removed.
2. Install new snap ring in groove at forward end of countershaft drive gear.
3. Press bearing cone on each end of countershaft, being sure that cone seats firmly against shoulder on countershaft.
4. Press direct and overdrive clutch gear on mainshaft, referring to marks made at disassembly.
5. Install overdrive gear on mainshaft with spur teeth toward clutch gear.
6. Slide spacer washer over splines and into place at overdrive gear hub. Turn washer in groove to align internal teeth with mainshaft splines so washer cannot be moved endwise. Insert lock in place between splines to hold washer in place.
7. Install low speed gear on mainshaft with spur teeth toward rear end of mainshaft.
8. Install low speed clutch gear with flat side of gear toward low speed gear.
9. Install shift sleeves on clutch gears.
10. Install drive gear bearing cup in case. Use new gasket and bolt bearing cap in place.
11. Press bearing on drive gear and slide sleeve into place against bearing.
12. Place original quantity of shims at outer end of sleeve. Then from inside of case, move drive gear and bearing in place in bearing cap.
13. Install drive gear front bearing and washer over outer end of drive gear. Then install flange and nut. While tightening flange nut, check bearing adjustment by turning drive gear by hand. If any binding or tightness is noted, it indicates an insufficient number of shims. Install sufficient number of shims to permit drive gear to be turned easily by hand but not so loose as to be able to spin.
14. If no tightness is evident with original shim pack in place, tighten flange nut to a minimum torque of

240 lb. ft. Recheck bearing adjustment by rotating drive gear. Shims are available in three sizes (.003″, .010″ and .030″) to establish proper bearing adjustment.

15. When proper shim pack has been selected, remove drive gear from bearing cap and lay shim pack aside for use when reassembling transmission.

Transmission, Assemble

1. If drive gear bearing cap is removed, bolt cap in place, using new gasket with oil passages aligned with passages in cap and case.
2. Install mainshaft inner bearing cup and countershaft front bearing cup.
3. Install countershaft assembly in case.
4. Install countershaft rear bearing cup, using same thickness of shims removed during disassembly. Install cap and tighten bolts, meanwhile turning countershaft by hand. If any binding is noted, remove bearing cap and add sufficient shims to provide a free turning countershaft with no end play. Three sizes of shims (.003″, .010″ and .030″) are available for use in obtaining proper adjustment of countershaft bearings.
5. Install drive gear and bearing in bearing cap, using shim pack previously selected.
6. Before installing propeller shaft flange, be sure washer is in place and install new oil seal with seal lip pointing inward.
7. Install front support bracket on trunnion at bearing cap. Tighten flange nut 240 lb. ft. minimum and install cotter pin.
8. Install mainshaft front bearing on pilot at front of mainshaft.
9. Lower mainshaft in case. Install rear bearing with shielded side toward front.
10. Install speedometer drive gear.
11. Install new oil seal in mainshaft rear bearing cap with lip of seal pointing inward. Also assemble speedometer driven gear in cap if this part has been removed.
12. Be sure snap ring is in groove in bearing, then install bearing cap, using new gasket.
13. Install flange and nut, tightening nut to 240 lb. ft. minimum.
14. Move shift forks to neutral and install cover with new gasket, being sure shift forks enter grooves in shift or collars.
15. Install breather in cover.

6041 SERIES

4 Speed Auxiliary

Disassemble, Fig. 19

1. Remove transmission cover.
2. Remove both propeller shaft flanges.
3. Remove support from main drive gear bearing cap.
4. Remove countershaft rear bearing cap, noting number of shims under cap.

Fig. 19 Spicer Series 6041 four speed auxiliary

Fig. 20 Spicer Series 6031, 6231 three speed auxiliary transmission

5. Remove mainshaft rear bearing cap, oil seal, and speedometer driven gear in cap. Then remove oil seal and driven gear from cap and sleeve.
6. Remove main drive gear bearing cap with bearings, gear, seal and seal cap.
7. Remove speedometer drive gear.
8. With suitable puller, press mainshaft with front pilot bearing, overdrive gear snap ring, overdrive and direct clutch gear, collar and overdrive gear out through front of case, leaving first speed gear, first and second clutch gear and collar, and second speed gear and sleeve in case. Remove these items from case after removing mainshaft.
9. Remove mainshaft rear bearing.
10. Drive countershaft toward rear far enough to force rear bearing cup out of case. Using snap ring pliers, remove countershaft second speed gear snap ring from groove, slide second gear forward, then lift countershaft assembly out of case.
11. Remove countershaft front bearing cup from case.
12. Remove power take-off covers, and drain and filler plugs from case.
13. Disassemble sub-assemblies as required. If countershaft is to be disassembled, gears should be marked so that correct position will be known when installing.

Countershaft Assemble

1. Drive gear keys in countershaft slots. Then using arbor press and suitable driver, press countershaft overdrive gear and drive gear into place.
2. Install new snap ring in groove at forward end of drive gear.
3. Press cone on front end of countershaft, making sure that cone seats firmly against countershaft.
4. Install second speed gear front snap ring over end of countershaft and position snap ring in groove in countershaft.
5. Install second gear on countershaft, then position rear snap ring in groove.
6. Press bearing cone on rear end of countershaft, making sure cone seats firmly against countershaft.

Mainshaft Assemble

1. Place mainshaft in vise with front end up. Then apply heavy gear oil on bearing surfaces.
2. Install overdrive gear and overdrive and direct clutch gear with shoulder toward overdrive gear.
3. Install snap ring in groove at front end of mainshaft.
4. Install overdrive and direct clutch gear collar with external teeth toward front end of mainshaft.
5. Install mainshaft pilot bearing, using suitable bearing replacer.

Main Drive Gear Assemble

1. Apply transmission lubricant to bearings before installing.
2. Press bearing cups into cap and install inner bearing on drive gear. Then install bearing spacer on drive gear.
3. Place drive gear and bearing in arbor press with bearing spacer in place.
4. Apply pressure on front bearing inner race, using a piece of 2" diameter tubing about 4" long over end of shaft. Bearing cup should turn readily but not spin on shaft with pressure applied. If bearing adjustment is too loose or too tight, select correct spacer (available in several sizes). After correct spacer has been installed, remove assembly from press.
5. If seal has been removed from seal cap, press new seal in cap.
6. Place washer in position against bearing cone. Then install seal cap with new gasket. Install cap bolts and tighten securely.

Transmission, Assemble

1. Install countershaft front bearing cup in transmission case bore.
2. Lower countershaft assembly in case with rear end of shaft out through rear bearing bore. Then move assembly forward so that front bearing enters cup.
3. Install drive gear bearing cap temporarily with new gasket. Tighten cap screws evenly and firmly. Then slide countershaft second speed gear on shaft and install snap ring in groove ahead of second speed gear.
4. Install rear bearing cup. Using same thickness of shims as was removed at disassembly, install rear bearing cap temporarily. Tighten cap bolts, meanwhile turning countershaft by hand. If any binding of countershaft bearings is noted before cap bolts are fully tightened, remove cap and add shims. If cap bolts are tightened with a shim pack which is too thin, bearings will be damaged. Three sizes of shims (.003", .010" and .030") are available for use in adjusting countershaft bearings. Bearing adjustment is correct when countershaft can be turned without evidence of binding and without perceptible end play.
5. Remove main drive gear bearing cap. Lower mainshaft first speed gear, first and second clutch gear and collar, and second speed gear into case. Then guide mainshaft assembly through front of case and through gears. Slide second speed gear sleeve into hub of second gear through rear of case.
6. Using new gasket, install main drive gear bearing cap with main drive gear and bearings on front of case, guiding mainshaft pilot bearing into pocket of main drive gear. Tighten cap bolts securely.
7. Press mainshaft rear bearing onto mainshaft and into case, then place speedometer drive gear on shaft, with shoulder toward front of transmission.
8. Install mainshaft rear bearing cap and gasket and tighten capscrews securely.
9. Install propeller shaft flange on mainshaft and tighten nut to a torque of 350-400 lbs. ft.
10. Place transmission front support bracket on trunnion at bearing cap, install front flange and tighten nut to a torque of 350-400 lbs. ft.
11. Install cover, being sure that shift forks enter grooves in shift collars.
12. Install breather in cover, and drain plugs.

6031, 6231 SERIES

3 Speed Auxiliaries

Disassemble, Fig. 20

1. Take off the transmission cover and hand brake mechanism.
2. Pull off both universal flanges and oil slingers.
3. Remove countershaft bearing caps, noting the number of shims behind rear bearing.
4. Remove mainshaft rear bearing cap and oil seal.
5. Use a puller to remove cage and bearing assembly, noting number of shims behind the cap.
6. Remove main drive gear bearing cage, together with bearing and oil seal, noting thickness of shims used at this point.
7. Use a puller to remove oil seal and bearing cup from cage.
8. Push countershaft to rear, moving mainshaft back at the same time until countershaft rear bearing is free of case.
9. Separate mainshaft from main drive gear, leaving pilot bearing in drive gear. Then shift countershaft forward again, and lift mainshaft out of the case.
10. Push main drive gear into case and lift out.
11. Use puller to remove drive gear spacer and bearing.
12. To disassemble mainshaft, make shift sleeves and clutch gears for reassembly purposes and slip clutch sleeves from clutch gears. Remove retainer and snap ring from front end of shaft and use a puller, if necessary, to remove the clutch gear. If a puller is used, hold a cloth under the assembly to catch the rollers. This same precaution should be taken when removing the low speed gear.
13. Lift out the countershaft. If the countershaft gears are to be removed, release the snap ring from the front end and press the gears off one at a time (except low gear which is integral with the shaft.)

Reassemble

Reverse the order of the above procedure to assemble the transmission. When assembling the mainshaft, however, clamp it in a vise with its rear end up. Apply a liberal quantity of grease around the low speed gear bearing surface and assemble the rollers around the shaft.

Assemble the low speed gear over the rollers with the splined hub of the gear facing up. Slip the bearing spacer into the bore of the gear, pushing it down against the rollers, then assemble the other rollers in the same manner.

Install the low speed clutch gear with the splined end up, and the collar with the conical end up, pressing the gear and collar tight against the low speed gear. Now fasten the rear end of the shaft in the vise and assemble the overdrive gear and bearings in the same manner, using the high speed clutch gear and snap ring to hold the gear in place. Install the clutch sleeves over the gears according to the marks made during disassembly.

8031, 8035 SERIES

3 Speed Auxiliaries

Disassemble, Fig. 21

1. Remove transmission cover.
2. Lock mainshaft by placing gears in two speeds at same time, remove nuts and pull off both flanges.
3. Remove front bearing cap and bearing as a unit.
4. Remove washer from front end of countershaft.
5. Remove mainshaft rear bearing cap and pull speedometer drive gear and washer off mainshaft.
6. Move main drive gear forward as far as possible and force mainshaft and gears rearward, thereby forcing mainshaft rear bearing out of case.
7. Use a suitable puller to remove bearing from mainshaft.
8. Slide low speed shift collar off mainshaft and remove through rear of case.
9. Raise front end of mainshaft and lift from case, passing low speed gear teeth through power take-off gear teeth.
10. Move main drive gear rearward, forcing bearing out of bore. Then lift assembly out through top of case.
11. Remove countershaft rear bearing cap. Then push countershaft forward until front bearing is free of case, after which use puller to remove bearing.
12. Move countershaft rearward until rear bearing is out of case. Then remove snap ring and bearing from countershaft. The assembly may then be lifted out of the case by its front end.

Mainshaft, Disassemble

1. Support mainshaft assembly with front side of low speed gear on bed plate of arbor press.
2. Apply pressure on rear of mainshaft to force low speed clutch gear off mainshaft. Use care to prevent loss of needle bearings as mainshaft is pressed out of gear.
3. Grip mainshaft in vise with front end up. Then remove mainshaft pilot bearing from shaft, and remove clutch gear lock nut.
4. Set mainshaft in arbor press with flange on sleeve resting on bed plate. Press on front end of mainshaft to force sleeve with mainshaft overdrive gear and bearings and clutch gear off mainshaft.
5. Slide gear off sleeve, being careful not to lose bearings.

Mainshaft, Assemble

1. Place locating pin in hole in sleeve. Apply heavy grease on surface of sleeve to hold bearings in place. Then stand sleeve on end with flange down and arrange needle bearings and spacer around sleeve.

50 Direct and Overdrive Shift Fork
51 Shift Collar
52 Locating Pin
53 Mainshaft Overdrive Gear
54 Sleeve
55 Needle Bearings

TPM-1072

Fig. 21 Spicer Series 8031, 8035 three speed auxiliary transmissions

Use 63 bearings in each row. Carefully lower overdrive gear over sleeve with spur teeth toward front of mainshaft.
2. Hold mainshaft in vise with front end up. Then lower overdrive gear and sleeve assembly over front end of mainshaft, carefully guiding head of locating pin into milled slot of mainshaft. Press sleeve flange tightly against mainshaft shoulder.
3. Press direct drive clutch gear on mainshaft up against sleeve. Then install lock washer and nut. Tighten nut securely and bend lock washer against flats on nut.
4. Grip mainshaft in vise with rear end up. Apply heavy transmission grease on mainshaft surface contacted by low speed gear rollers. Then arrange two rows of needle bearings separated by a spacer around mainshaft. Use 63 rollers in each row.
5. Set low speed gear over bearings with spur teeth upward. Drop other spacer over rearward end of mainshaft and insert remaining 63 rollers at gear hub.
6. Install clutch gear on splines at rear of gear with flat side of gear toward front.
7. Install pilot bearing on forward end of mainshaft and install shift collar.

Transmission, Assemble

Reassembly procedure is largely the reverse of disassembly procedure. However, the following should be noted:

1. When installing main drive gear and mainshaft, place main drive gear in place from inside of case, moving the assembly forward as far as possible. Lower mainshaft and gears into case with rear end extending through rear bearing bore. Install low gear shift collar on clutch gear, inserting collar through bearing bore in case.
2. Move mainshaft forward so that mainshaft pilot bearing enters pocket of main drive gear. Then install rear mainshaft bearing, spacer washer and speedometer drive gear.
3. Be sure to install front bearing cap gasket so oil passage is not obstructed.
4. Companion flange nuts should be torque tightened to 240-310 lbs. ft.

8125 MODEL

This transmission, Figs. 22 and 23, is made semi-automatic to obtain twelve speeds forward and six reverse with only three shift lever positions. To accomplish the pre-selected but automatic shifts, air actuated power cylinders built into each end of the shifter housing are used to make the input gear splits and hi-lo range shifts. Air pressure that makes these shifts is admitted and exhausted from opposite ends of the double acting cylinders through a control valve operated by cables attached to the gear shift lever.

Transmission, Replace

1. Completely bleed pressure from all air tanks and drain lubricant from transmission.
2. Remove all cables, clamps, etc., that are necessary before transmission is removed.
3. Disconnect air line hose that connect to transmission air filter.
4. On tilt cab models, disconnect shift, selector, and forward and reverse remote cables or rods from transmission. On conventional models, remove shift lever tower assembly.
5. Disconnect speedometer cable.
6. Disconnect propeller shaft, clutch and brake controls.
7. Remove two plunger covers from rear of air control valve, Fig. 24. With splitter and range control cables shifted rearward, remove lock nuts and rubber ring from end of cables.
8. Loosen cable lock nuts at front of air control valve and pull cables free. Move cables clear of transmission.
9. Support transmission with jack or hoist, unfasten transmission from its mountings and pull it rearward and out of chassis.
10. Reverse foregoing procedure to install.

Disassembly

CONTROL COVER

1. Remove air inlet line from air control valve and air regulator.
2. Remove two cap screws and set bracket, filter and regulator aside.
3. Remove cover screws and hook a lifting sling to cover so it pivots and raises at an angle, Fig. 25. *Transmission must be in Lo-range gear position for range fork to clear forward and reverse interlock.*
4. Lift cover straight upward and remove shift fork shoes to prevent their loss in transmission.

MAINSHAFT

1. Remove clutch housing.
2. Lock transmission in two gears, Fig. 26. Also, place transmission forward and reverse shift rod in forward gear position (rod pushed inward).
3. Loosen Hi-range countershaft lock nut.
4. Remove main drive gear bearing lock nut, Fig. 27. *Do not remove main drive gear retaining nuts at this time.*
5. Remove U-joint flange from rear end of transmission.
6. Remove mainshaft rear bearing cap, Lo-range countershaft rear bearing cap and oil pump cover. Install two spacers and lock nuts to Lo-range countershaft rear bearing cap studs, then remove rear bearing lock nut. Remove lock nuts, spacers and rear bearing retainer.
7. Use a suitable puller to remove mainshaft rear bearing retainer. Take off bearing and retainer, oil ring and spacer.
8. Support mainshaft as shown in Fig. 28.
9. Remove main drive gear bearing retainer with a puller.
10. Remove snap ring and press out drive gear bearing.
11. Remove thrust washer and lift main drive gear stem toward upper left corner of housing and pull front drive gear through housing opening.
12. Remove mainshaft assembly from housing, Fig. 28.

HI-RANGE COUNTERSHAFT

1. Remove oil pump from rear of transmission.
2. Remove Hi-range countershaft shift fork and rod.
3. Remove front drive gear snap ring from Hi-range countershaft and slide gear back on shaft as far as possible.
4. Attach lifting sling to Hi-range countershaft, Fig. 29. Then pry Hi-range countershaft, including front bearing retainer out of housing, Fig. 29.
5. After Hi-range countershaft is out far enough to attach puller, remove lock nut and thrust washer and pull retainer and bearing off shaft.
6. Remove Hi-range countershaft rear bearing retainer.

LO-RANGE COUNTERSHAFT

1. Remove forward and reverse shift fork set screw.
2. Remove forward and reverse poppet, Fig. 30.
3. Remove forward and reverse shift rod, fork, spacer and oil seal.
4. Use puller to remove Lo-range countershaft rear bearing retainer.
5. Remove gear spacer and gear from Lo-range countershaft. Remove assembly from housing.
6. Remove front bearing retainer and press bearing out of retainer.

REVERSE IDLER GEAR

1. Remove lock plate from housing.
2. With a long drift, Fig. 31, drive idler gear shaft out of housing, and lift assembly from housing.

Disassembly of Sub-Assemblies

CONTROL COVER—Disassemble control cover, splitter cylinder and range cylinder as suggested by Figs. 32, 33 and 34.

MAINSHAFT ASSEMBLY

1. If splitter synchronizer was not removed when mainshaft was removed from housing, slide synchronizer off mainshaft.
2. Place synchronizer on bench and pull up on bronze ring to remove blocker shafts from clutch gear. Watch for poppets and springs. Accomplish same procedure for other side of synchronizer.
3. Remove Lo-range and reverse gear and range synchronizer from mainshaft.
4. Place range synchronizer on bench with small bronze ring up. Lift upward to remove ring from clutch gear. Watch for poppets and springs.
5. Compress three synchronizer poppets back into clutch gear, using a small screwdriver or similar tool, Fig. 35. Pull clutch gear from large bronze ring, using care not to lose poppets and springs.
6. Place mainshaft in vise with soft jaws and unstake clutch drive gear lock nut.
7. Remove mainshaft lock nut and tap shift collar to loosen bearing cone.
8. Remove bearing cone, clutch drive

Fig. 23 Spicer 8125 transmission

Fig. 22 Spicer 8125 transmission shift control

gear, spacer, shim pack and spacer. Wire shim pack together and put aside for reassembly.

9. Remove 5-6, 11-12 synchronizer from cluster gear.
10. Remove second clutch drive gear bearing cone and cluster gear by tapping on cluster with soft hammer. It may be necessary to remove these parts by means of an arbor press.
11. Remove cluster gear snap ring and press bearing cups, spacer and cone free of cluster gear.

HI-RANGE COUNTERSHAFT

1. Place Hi-range countershaft in a vise.
2. Remove rear lock nut, rear bearing outer race and roller assembly.
3. Shift Hi-range synchronizer into 1-2, 7-8 gear position. Using a brass drift, tap shifting collar and steel synchronizer cone to remove rear bearing inner race.
4. Remove rear thrust washer; then slide 1-2, 7-8 speed gear from countershaft.
5. Remove synchronizer.
6. Remove both inner and outer front drive gear snap rings and slide gear from countershaft.
7. Press countershaft out of rear drive gear. *Do not attempt to press gear off by supporting on 3-4, 9-10 speed gear as the Woodruff key will not clear this gear.*
8. Remove Woodruff key and slide 3-4, 9-10 gear from countershaft.

Fig. 25 Removing control cover. Model 8125

LO-RANGE COUNTERSHAFT

1. Place assembly in a vise and pull off front bearing inner race.
2. Remove snap ring and press shaft out of drive gear.

Fig. 24 Air control valve components. Model 8125

Fig. 26 Position of synchronizers and shift rods to lock transmission. Model 8125

Fig. 27 Removing main drive gear lock nut. Model 8125

Fig. 28 Lifting mainshaft assembly from housing. Model 8125

Assemble Sub-Assemblies

LO-RANGE COUNTERSHAFT, Fig. 36

1. Tap Woodruff key into shaft and support drive gear on arbor press with long hub up. Align keyway and press shaft into gear.
2. Assemble snap ring to shaft and set in groove with drift. Tap inner bearing race on front of shaft with flange toward gear.
3. Position forward and reverse clutch gears on shaft with fork collar toward drive gear.
4. Press front bearing in retainer and assemble bearing and retainer to transmission boss. Torque cap screws to 20-25 ft. lbs. and secure with lock wire.

HI-RANGE COUNTERSHAFT, Fig. 37

1. Coat bore of 3-4, 9-10 speed gear with Lubriplate or equivalent and assemble to countershaft. Place shaft in vise and tap Woodruff key into position.
2. Place rear drive gear on shaft so that keyway in gear aligns with key in shaft. Press gear on shaft.
3. Install snap ring to secure rear drive gear on countershaft. Place front drive gear rear snap ring on shaft and slide back against rear drive gear snap ring.
4. Place countershaft in vise. Install front drive gear and snap ring. Coat clutch teeth of 3-4, 9-10 gear splines of countershaft and clutch teeth of synchronizer with Lubriplate.
5. Assemble synchronizer to shaft and coat external teeth with Lubriplate.
6. Coat 1-2, 7-8 gear and fluted bearing with Lubriplate. Assemble gear to shaft and install thrust washer with flat side toward gear.
7. Place inner race of bearing on shaft with flange toward thrust washer and tap into position.

Fig. 30 Forward and reverse shift rod poppet. Model 8125

8. Place outer race and rollers of rear bearing on inner race and install lock nut. Tighten lock nut to 350-400 ft. lbs. and stake nut to countershaft.
9. Place rear bearing retainer in bearing bore at rear of housing. Install cap screws and tighten evenly until retainer is in proper position. Then torque screws to 30-35 ft. lbs. and secure with lock wire.

MAINSHAFT ASSEMBLY, Fig. 38

1. Place cluster gear on arbor press and install tapered roller bearing cone in cluster gear face up.
2. Start cluster gear bearing cup in gear with tapered face down. Place bearing spacer on cup. Place second bearing cup on spacer with tapered face up.
3. Using suitable tool in arbor press, press bearing cups and spacer into cluster gear.
4. Install snap ring with tapered side

Fig. 29 Prying Hi-range countershaft from housing. Model 8125

Fig. 31 Driving reverse idler gear shaft out of housing. Model 8125

Fig. 35 Compressing poppets into clutch gear. Model 8125

Fig. 32 Exploded view of control cover. Model 8125

Fig. 33 Exploded view of splitter cylinder. Model 8125

Fig. 34 Exploded view of range cylinder. Model 8125

up in groove flush with end of bearing cup.

5. Assemble bearing spacer, shim pack, and spacer in cluster gear. Place rear bearing cone in cluster gear, centering on bearing spacer.
6. Using arbor press, apply light load on bearing cone. Check for free rotation of gear, Fig. 39. If gear will not rotate or does not rotate easily, add shim to pack. If gear spins freely, check for end play and add or remove shims as required to obtain zero end play.
7. Place mainshaft clutch gear bearing cone on cluster gear and bearing spacer with tapered face up. Set bearing spacers and shim pack on bearing, Fig. 40.
8. Place clutch gear over bearing and spacers. Place front bearing cone in gear and check for free rotation and end play as explained above.
9. Place mainshaft on arbor press with pilot bearing end up. Remove rear bearing cone from cluster gear and press on mainshaft with tapered face up.
10. Remove spacers and shims from cluster gear and assemble on mainshaft. Place cluster gear on mainshaft with large diameter down.
11. Place cluster and clutch gear bearing spacer in cluster gear. Press on bearing spacer to force bearing cone onto mainshaft.
12. With pressure applied to gear, recheck for preload and end play.
13. Place 5-6, 11-12 synchronizer on cluster gear. Remove bearing cone from clutch gear and press on mainshaft. Remove spacers and shims from clutch gear and install on mainshaft.
14. Set clutch gear on bearing cone and press front bearing cone on mainshaft.
15. With pressure still applied to bearing cone, recheck for preload and end play.
16. Install lock nut on mainshaft and torque to 400-450 ft. lbs.
17. Check clutch gear bearing preload as shown in Fig. 41. Preload should not exceed two pounds load. *While making test, hold 5-6, 11-12 synchronizer back to eliminate drag. If preload is not within limits, adjust shim pack as necessary.*
18. Check cluster gear preload in same manner except preload should not exceed three pounds load.
19. Stake lock nut in groove of mainshaft.
20. Assemble range synchronizer by placing Lo-range bronze cone on bench and setting synchronizer clutch gear on blocker shafts with external teeth up. Assemble three poppets and springs to three offset holes in clutch gear.
21. Rotate and set clutch gear down over blocker shaft, making sure pins are inserted in chamfered openings on bottom side of clutch gear.
22. Assemble three remaining poppets and springs.
23. Position Hi-range bronze blocker

Fig. 36 Exploded view of Lo-range countershaft assembly. Model 8125

Fig. 39 Checking free rotation and end play of mainshaft cluster gear. Model 8125

Fig. 40 Assembling mainshaft drive gear components. Model 8125

Fig. 37 Exploded view of Hi-range countershaft assembly. Model 8125

Fig. 42 Positioning interlock pin in cross hole of Hi-range countershaft shift rod. Model 8125

Fig. 43 Installing 5-6-11-12 shift rod. Model 8125

Fig. 38 Exploded view of mainshaft assembly. Model 8125

pins in synchronizer clutch gear openings. Depress poppet springs with small drift and slide pins down in clutch gear.

24. Check shift of synchronizer high and low positions by shifting clutch gear collar up and down. Clutch gear should bottom against bronze cones with each shift.
25. Coat splines and fluted bearing on mainshaft as well as clutch teeth of synchronizer and clutch gear with Lubriplate.
26. Assemble range synchronizer to mainshaft. Coat teeth of synchronizer and Lo-range and reverse gear with Lubriplate.
27. Install Lo-range and reverse gear on mainshaft.
28. Assemble splitter synchronizer by placing bronze cone on bench and setting synchronizer clutch gear on blocker shafts. Assemble three poppets and springs, one to every other hole in clutch gear. Assemble clutch gear to bronze cone by depressing poppets and springs with small drift and sliding clutch gear down on blocker shafts.
29. Accomplish same procedure for assembling other bronze ring to synchronizer clutch gear. After synchronizer is assembled, check shift by pulling up squarely on clutch gear until it bottoms against bronze cone. Turn synchronizer over and repeat shift in opposite direction.

CONTROL COVER (See Figs. 32, 33, 34)—Assemble the control cover in the reverse order of disassembly, observing the following precautions:

Fig. 41 Checking mainshaft clutch gear bearing preload. Model 8125

Fig. 44 Installing range air cylinder base. Model 8125

VIEW A

VIEW B

VIEW C

VIEW D

Fig. 45 Setting adjustable interlock to reduce end play of shift forks. Model 8125

1. Torque set screws to 45-50 ft. lbs.
2. Position interlock pin in cross hole of Hi-range countershaft shift rod as shown in Fig. 42.
3. Install 5-6-11-12 shift rod as shown in Fig. 43.
4. Assemble interlock bridge so chamfered edge is toward shift rods.
5. Check operation of interlock system by moving shift rods to the right. Adjustable interlock must rise when shift rods are moved.
6. With air cylinder base positioned on control cover, push base against mounting face and check for air gap at point "A", Fig. 44. Also check alignment of Allen head retaining screw openings in base with threaded holes in cover. If base seats flush without air gap but screw holes do not align, remove metal from area "A", Fig. 44 (right view), to eliminate air port boss interference. If air gap exists then, remove metal from area "B" to secure flush mounting.

Fig. 46 Checking clearance between air control valve and control cover. Model 8125

SETTING ADJUSTABLE INTERLOCK—The adjustable interlock must be set to reduce end play of the range and splitter shift forks when they are locked in their "Hi" and "Lo" positions. The interlock length must also be checked in neutral with range and splitter shift forks midway of travel, or neutral. A tight adjustment in neutral will cause slow range and splitter shifts plus hard shifting of manual positions. To adjust, proceed as follows, Referring to Fig. 45.

1. Move range and splitter shift forks to outboard position (View A). Move Hi-range countershaft shift rod to right or left of neutral. Remove preselection valve from air control valve and set it in position on control cover to pilot interlock.
2. Lengthen interlock by holding rod and unscrewing head counterclockwise until it fits snugly against chamfered surface of the bridge (View B).

3. Check end play of range shift fork in the outboard position (View C). End play should not exceed $\frac{1}{16}$" total.
4. Check end play of splitter shift fork in the outboard position. It should be approximately the same as the range shift fork. If splitter end play is less, or zero, remove air cylinder base and measure length of the pilot, which should be $1\frac{1}{32}$".
5. Shift Hi-range countershaft to mid-point or neutral position. Move range and splitter forks to neutral point. To position them in neutral, align edge of rod notches with end of center boss (View D). Bridge must be free. If shift forks cannot be moved to neutral, the interlock is too long. Shorten it only enough to free up the bridge at this neutral position.
6. Move range and splitter forks to the inboard position and check end play of shift forks. End play should not exceed $\frac{1}{16}$" for either fork.
7. Recheck interlock setting in all positions. Interlock should not bind with the chamfer of the bridge. Check by rotating with fingers.
8. When final adjustment has been made, tighten set screw securely. A suitable bonding agent should be used to prevent screws from loosening. Secure fork set screws with lock wire.

AIR CONTROL VALVE CLEARANCE, Fig. 46—After installing a new O-ring seal to the pre-selection valve, lubricate the valve and assemble it to the air control valve. Assemble air control valve on the two housing studs. With either fork out of neutral, and nuts *not* installed, a gap of $\frac{1}{16}$" to $\frac{3}{32}$" should exist between the valve body and the control lever. This gap represents the preload of the pre-selection valve spring. If gap is less than $\frac{1}{16}$", check the pre-selection valve seat or interlock system for excessive wear.

Assemble Transmission

The transmission is assembled in the reverse order of disassembly. The sub-assemblies are installed in the following order:

1. Reverse idler gear assembly.
2. Lo-range countershaft assembly.
3. Hi-range countershaft assembly.
4. Mainshaft assembly.
5. Control cover.

Trouble Shooting Off Vehicle

The off vehicle trouble shooting is a series of checks that must be performed before the transmission is installed in the vehicle. Refer to Fig. 47 and proceed as follows:

1. Place transmission on bench and connect air hose to inlet port of air filter.
2. Remove pipe plug from top of air control valve and install pressure gauge.
3. Install suitable type cables in air control valve so splitter and range can be operated manually.
4. With remote control shift lever in neutral, pressure gauge should read 70 to 75 psi. If below, disassemble pressure regulator and add shims under spring until specified 70-75 psi reading is obtained.
5. Place shift lever in any gear position. Air pressure should bleed down slowly to zero; if necessary move range cable in and out to exhaust air from system. If gauge does not read zero after this operation, the pre-selection valve leaks.
6. With shift lever in one of the manual shift positions, pre-select range shift by moving top cable forward. Push bottom cable (selector cable) rearward. Move shift lever to neutral and rotate drive shaft by hand to complete range shift. Range shift will be audible and complete if shift lever can be moved back into gear.
7. Complete several high and low range shifts to make sure shift is operating properly.
8. With shift lever in one of the manual shift positions, pre-select splitter shift by moving bottom cable forward (push range cable rearward).
9. Move shift lever to neutral and rotate drive shaft by hand to complete splitter shift. The splitter shift will be audible and complete if shift lever can be moved back into gear.
10. Complete several splitter shifts to make sure shift is operating properly. If operation of range and splitter shifts are correct, and no air leakage is evident, install transmission in vehicle in reverse order of its removal.

Fig. 47 Checking operation of range and splitter shifts. Model 8125

Trouble Shooting On Vehicle

SHIFTING COMPLAINTS—Abnormal shifting is not necessarily caused by the transmission itself. This is sometimes caused by inadequate lubrication, improper adjustment, or defective parts of the remote control linkage and gearshift island controls. Before attempting to trouble shoot the transmission, make certain that the remote control cables or rods are operating properly and are adequately lubricated. If they are, check the transmission as follows:

AIR PRESSURE SETTING CHECK

1. Start engine and build up air pressure to full line pressure.
2. Shut off engine and place shift lever in 5-6-11-12 gear position.
3. Remove pipe plug from top of air control valve and install pressure gauge in pipe plug opening (see Fig. 47).
4. Move shift lever into neutral and check pressure gauge reading. If reading is not between 70 and 75 psi, adjust pressure regulator by disassembling and adding shims under spring until proper pressure is obtained.

AIR CONTROL SYSTEM CHECK—With air pressure gauge still installed and with correct reading of 70-75 psi, shift transmission back into 5-6-11-12 gear position. This shuts off the air inlet supply and gauge reading will start to fall off toward zero. However, if air pressure stays up, move range "T" handle up and down slowly to exhaust air trapped in range and splitter air cylinders. Air pressure should drop and stay at zero. If gauge rises from zero reading, the pre-selection valve in the air control valve is leaking and must be repaired or replaced.

If pressure bleeds off and remains at zero, then place shift lever back into neutral and check for air leaks at the four exhaust ports on rear of control valve. Check for leakage by covering exhaust ports with fingers. Slow or minor leaks are acceptable. However, audible or excessive leakage must be corrected. Air leaking out exhaust ports can originate in air cylinders as well as the control valve.

WARNER TRANSMISSIONS

T9, T97 SERIES

Disassemble, Fig. 1

1. Take off the transmission cover.
2. Unscrew the nut from the universal flange.
3. Remove the hand brake mechanism.
4. Remove universal flange.
5. Remove main drive gear bearing retainer and pull drive gear out through front.
6. Take off mainshaft rear bearing retainer oil seal and speedometer drive gear.
7. Before removing the mainshaft, chalk-mark the relationship of the mainshaft splines with the mating splines in the sliding gears so that these parts may be assembled in the original position, as the gears are a selective fit on the mainshaft splines.
8. Grasp the mainshaft gears and pull the mainshaft and rear bearing out through the rear. Then lift out the loose gears.
9. Remove the counter shaft lock plate, push the shaft through the rear and lift out the cluster gear.
10. Drive out the reverse shift rail and lift out the fork.
11. Push the reverse idler shaft out through the rear and lift out the gear.

Index & Lube Capacity

Model	Speeds	Oil, Pts.	Page
T9, T9A	4	6	164
T85	3		164
T87D	3	6	165
T87E	3	5½	165
T89B	3	3	166
T89C	3	3½	166
T97	4	7	164
T98, T98A	4	8	168

Reassembly

Reverse the order of the above procedure to assemble the unit. And when installing the mainshaft, be sure to match the marked gear splines with the mainshaft splines.

T85 SERIES

Three Speed, Fig. 2

1. To disassemble, remove gearshift housing.
2. Remove mainshaft nut and parking brake.
3. Remove U-joint flange, speedometer gear and spacer.
4. Remove mainshaft and rear bearing retainer rearward out of case as a unit.
5. Remove mainshaft pilot bearing.
6. Remove main drive gear bearing retainer. After removing large snap ring, tap drive gear and bearing back into case, removing it through rear of case.
7. Drive countershaft backward out of case and remove cluster gear assembly.
8. Remove reverse idler gear.
9. To disassemble mainshaft, remove snap ring from its front end. Mark relationship of synchronizer hub and sleeve and slide synchronizer and gears off shaft.

Assemble Transmission

1. Install reverse idler gear and shaft with chamfered teeth ends toward front.
2. Install cluster gear assembly in bottom of case. Tang on front washer fits into slot in case thrust face. Tab on rear steel washer must be up.
3. Install main drive gear bearing and snap ring from front until snap ring bottoms on case.
4. Install drive gear retainer without gasket and finger tighten retainer bolts.
5. Install oil slinger on drive gear shaft with grease and with dished side away from bearing.
6. Install drive gear shaft with oil slinger in case and shaft into bearing.
7. Remove drive gear retainer and install spacer washer and thickest snap ring that will fit.. Snap rings are available in thicknesses of .086" to .103".
8. Tap drive gear shaft forward out of case as far as gear will allow. Then install mainshaft pilot in bore of drive gear, using grease to hold rollers in place.
9. Install synchronizer stop ring on rear end of drive gear shaft, coating inside of stop ring with grease.

Assemble Mainshaft

1. Press rear bearing on mainshaft. Install rear snap ring into rear bearing retainer housing and tap mainshaft with bearing into retainer. Install thickest snap ring that will fit in front of rear bearing. Snap rings are available in thicknesses of .088" to .100".
2. Assemble gears and synchronizer on mainshaft. Grease synchronizer stop ring before assembling, and make sure stop rings are free.
3. Install mainshaft, being sure that one of the pilot bearings is not forced off position and block oil hole in mainshaft.
4. Tap main drive gear to rear until snap ring seats on case.

Final Assembly

1. Turn transmission to help align cluster gear to install countershaft.

Fig. 1 Warner T9, T97 Series four speed transmission

Fig. 2 Warner T85 Series three speed transmission

2. When countershaft is close to end of case, install key and drive it into case.
3. Turn rear bearing retainer into position and torque retainer bolts to 65-75 ft. lbs.
4. Install new gasket on main drive gear bearing retainer, install retainer and torque bolts 25-30 ft. lbs. Select gasket or gaskets that will seal lubricant and prevent end play between snap ring and retainer. Gaskets are available in thicknesses of .10″ to .025″.
5. Install spacer, speedometer drive gear and flange.
6. Install parking brake.
7. Shift transmission into neutral. Place 2nd-3rd fork on clutch gear sleeve and place gearshift housing with new gasket on case.

Gearshift Linkage

For any adjustment to bring shift lever to horizontal plane with lever in neutral position, adjust length of 2nd-3rd control rod at its swivel.

The crossover movement of lever should be made without binding or interference. If slots in lever are not aligned, the gearshift tube pin strikes corner of slot. To bring slots in line, adjust low-reverse rod.

T87 SERIES

Three Speed, Figs. 3 and 4

1. Remove gearshift housing.
2. Remove parking brake.
3. Remove mainshaft bearing retainer.
4. Drive countershaft out through rear of case.
5. Use puller to remove mainshaft bearing.
6. Remove input shaft retainer and tap shaft and bearing as far forward as possible.
7. Remove mainshaft assembly.
8. Remove input shaft. If bearing is to be replaced, assemble with thickest snap ring that will fit.
9. Use puller to remove reverse idler shaft.
10. Remove reverse idler gear and countershaft gear cluster.

Assemble Transmission

1. Install reverse idler gear and shaft.
2. Install cluster gear assembly with front thrust washer tip hooked into groove on inside of case. Check end play (.006-.020″). Change thrust washers as required.
3. Install assembled mainshaft. Place a short 2 x 4 block between input shaft and mainshaft. Slide mainshaft bearing baffle and bearing onto shaft. Baffle must be installed so it does not rub bearing outer race. Drive bearing onto shaft.
4. Install mainshaft pilot rollers in input shaft, holding them with grease.
5. Place front blocking ring on synchronizer and start input shaft bearing in case.
6. Drive mainshaft bearing into case.
7. Tap input shaft and bearing into place. Install retainer without gasket and tighten bolts to bottom retainer on snap ring. With feeler gauge, check clearance between gasket surface and case. Select a gasket or gaskets that will seal oil and eliminate all clearance.
8. Raise cluster gear and insert countershaft. Then install retainer in notches in countershaft and reverse idler shaft. Drive both shafts toward front so that retainer is tight against gasket and torque bolts to 25-37 ft. lbs.
9. Install speedometer gear and spacer, mainshaft bearing retainer and gasket, and parking brake. Tighten output shaft nut to 90-125 ft. lbs.
10. Install gearshift housing.

Fig. 4 Warner T87 Series gearshift housing

Fig. 6 Warner T89 Series gearshift housing

Fig. 5 Warner T89 Series three speed transmission

T89 SERIES

Three Speed, Figs. 5 and 6

1. Remove gearshift housing.
2. Remove parking brake.
3. Tap main drive gear forward as far as possible.
4. Push countershaft out of rear of case.
5. Remove mainshaft assembly.
6. Remove main drive gear; then bearing.
7. Drive reverse idler gear shaft out of rear of case.
8. Lift out countershaft gear cluster.
9. Disassemble mainshaft.

Assemble Transmission

1. Place assembled countershaft gear cluster in case. Tang on front thrust washer fits into slot in case surface. Tab on rear steel washer must be up.
2. Install countershaft. Check end play (.006-.020"). Change thrust washers as required.
3. Install reverse idler gear shaft with chamfered teeth ends to front. Drive shaft in nearly flush with case and insert Woodruff key.
4. Tap input shaft bearing in case until snap ring bottoms in case. Install bearing retainer without gasket and barely tighten retainer capscrews. Lightly coat baffle with grease to hold it in place and install it on input shaft at rear of bearing with dished side away from bearing. Drive shaft into bearing with hard wood block.
5. Remove input shaft bearing retainer and install spacer washer and snap ring on input shaft. Install thickest snap ring that will fit. Then tap input shaft as far forward as possible and install pilot bearing rollers, holding them with grease.

Fig. 7 Warner T98 Series four speed transmission

6. Install mainshaft and bearing in bearing retainer casting, using the thickest snap ring that will fit.
7. Assemble mainshaft and secure with snap ring at front of shaft.
8. With new gasket, install mainshaft rear bearing retainer.
9. Tap input shaft bearing toward rear until outer snap ring bottoms on case.
10. Install countershaft gear cluster and insert Woodruff key in countershaft.
11. Torque mainshaft rear bearing retainer bolts to 65-75 ft. lbs.
12. Install and tighten input shaft bearing retainer to 25-30 ft. lbs., using a gasket or gaskets that will seal lubricant and prevent end play between snap ring and retainer.
13. Install parking brake.
14. Install shift housing cover with new gasket.

T98 SERIES

Four Speed, Figs. 7 and 8

1. Remove parking brake.
2. Remove mainshaft bearing retainer.
3. Remove countershaft-reverse idler shaft lock.
4. Remove gearshift housing.
5. Remove mainshaft bearing.
6. Remove input shaft bearing.
7. Drive out countershaft.
8. Remove input shaft through front end of case.
9. Pull out reverse idler shaft.
10. Remove reverse gear shifter arm from case.
11. Remove mainshaft assembly through top of case.
12. Remove power take-off cover and roll cluster gear toward top of case until small end of assembly can be pushed through mainshaft bearing bore in case.

Assemble Transmission

1. Position case with power take-off opening downward.
2. Hold thrust washer at front end of inner thrust plate at rear end of cluster gear to prevent rollers from falling out of gear. Position gear in bottom of case and install outer thrust plate.
3. Install reverse idler gear and shaft with slot in end of shaft down at rear face of case.
4. Install countershaft through cluster gear with slot in end of shaft facing downward. Cluster gear end play should be .006-.020". Change thrust washers as required.

5. Install pilot rollers in input shaft. Place baffle on shaft so it does not rub bearing race. Position input shaft in bore of case, working from inside of case. Install high speed synchronizer blocking ring on input shaft gear.
6. Install mainshaft assembly, inserting forward end in input shaft. Use a stop yoke tool over synchronizer rings to prevent jamming rings.
7. Install input shaft bearing and install thickest snap ring that will fit.
8. Install input shaft and bearing in case and install snap rings on both bearings.
9. Install input shaft retainer without gasket. Tighten bolts enough to bottom retainer on snap ring. Measure clearance between retainer gasket surface and case and select a gasket or gaskets that will seal oil and eliminate clearance. Tighten bolts to 25-30 ft. lbs.
10. Slide second speed synchronizer to rear and install reverse gear shifter arm.
11. Install reverse idler shaft-countershaft retainer and gasket. Torque retainer bolts to 25-37 ft. lbs.
12. Install speedometer gear and spacer, mainshaft bearing retainer and gasket. Make sure longest retainer bolt is in proper hole. Torque bolts to 25-35 ft. lbs.
13. Install gearshift housing and torque bolts to 30-35 ft. lbs.
14. Install U-joint flange and parking brake drum. Torque mainshaft nut to 90-125 ft. lbs.

Fig. 8 Warner T98 Series gearshift housing

LOCKING DIFFERENTIALS

THE MAIN PURPOSE of these differentials is that they supply a greater percentage of torque to the wheel with better traction and still furnishes to the wheel with poorer traction as much torque as it is able to absorb under the circumstances.

In the conventional differential the wheel easiest to turn receives the power. Therefore, when traction conditions under the rear wheels are not the same, the driving force is limited by the wheel with the poorer traction (easiest to turn) even though one wheel is on good traction surface.

These locking differentials do not permit shock loads or full engine torque to be transmitted to one axle shaft. They provide power to both rear wheels and maintain the differential action that is necessary when the vehicle is turning a corner to permit the outer wheel to turn faster than the inner wheel.

Service Note

"On car" type wheel balancers are not recommended for use on rear wheels of cars equipped with a locking differential. The rear wheel will drive if in contact with the ground or with a block even though the opposite wheel is raised. *However, this type of wheel balancer may be used by removing the wheel opposite of the one being balanced with the complete assembly raised.*

POWR-LOK

Fig. 1 shows the cone clutch type whereas Fig. 2 illustrates the plate clutch type. Each assembly consists of two case halves, two cross pins held together by a thrust block, differential pinions, side gears, and clutch rings (Fig. 1) or clutch plates (Fig. 2).

The cross pins are made with a movable joint at the center to permit each one to move independently while in continuous engagement. The pin ends are made in the form of a V, and a similar V is machined in each case half to provide a ramped cam surface.

In Fig. 1, the clutch ring is fitted over each bevel side gear and mates with a cone surface machined in each half of the differential case.

In Fig. 2, the clutch plates operate between the flat surface on the clutch retainer and the machined surface in each half of the differential case.

Operation

As the vehicle is put in motion, the driving force moves the cross pin up the ramp of the cam surface, applying a load to the clutches and restricts turning of the differential through the friction of the clutches on the mating surfaces in the differential case, Fig. 3. This provides a torque ratio between the axle shafts which is based on the amount of friction in the differential and the amount of load that is being applied to the differential.

When turning a corner this process is, in effect, partially reversed, Fig. 4. The differential gears become a planetary gear set, with the gear on the inside of the curve becoming the fixed gear of the planetary. The outer gear of the planetary overruns as the outside wheel on the curve has a further distance to travel. With the outer gear overrunning and the inner gear fixed, the differential pinions are caused to rotate, but since they are restricted by the fixed gear, they must first move the cross pins back down the cam surface, relieving the thrust load of the clutch on its mating surface in the differential case. Thus when turning a corner, the differential,

Fig. 1 Cone clutch type of POWR-LOK differential

Fig. 2 Plate clutch type of POWR-LOK differential

Fig. 3 Differential action when moving straight ahead

Fig. 4 Differential action when turning a corner

Fig. 5 Plate clutch type of POWR-LOK differential (4 stack unit) with Belleville spring plates at outside of stacks.

for all practical purposes, is similar to a conventional differential and the wheels are free to rotate at different speeds.

With locking differentials, certain characteristics must be taken into consideration. Under average driving conditions, such as straight ahead, reverse, extreme right and left turns, the operation will be the same as with the conventional differential. However, a little more backlash may be noticed due to the lateral movement of the differential cross pins. In addition, a slight chatter may occur under surge torque with one wheel on a slippery surface. These conditions are considered normal.

CAUTION—Do not attempt to spin a wheel under power with a jack under only one side; both wheels must be clear of the ground. If one wheel remains in contact with the ground, there is a possibility that when spinning the other wheel, friction of the clutch rings or clutch disc may set the vehicle in motion.

Servicing Cone Clutch Type

This type differential, Fig. 1, must be replaced as a unit as individual parts are not available. It is furnished less ring gear and side bearings.

Servicing Plate Clutch Type

Before disassembling the differential, scribe a line across the differential case halves for alignment upon reassembly. Then, after removing the attaching bolts, separate the case halves and remove the differential parts.

Note the relative position of the friction plates, friction discs and Belleville spring plates (if used) so that they may be reassembled in the proper sequence, Figs. 5, 6 and 7.

Inspect all parts. See that there are no worn, cracked or distorted clutch plates. All parts must be free of nicks, burrs or any imperfections that will reduce the efficient operation of the unit.

1. Assemble differential as suggested in Figs. 5, 6 and 7.
2. Make sure the side gear retainer will rotate with a slight drag when in the case. Repeat for opposite side.
3. Install side gear on ring gear flange half.
4. With ring gear flange half in a vertical position, install one shaft and gears, making certain that notch in shaft is up.
5. Install side gear in other half of case.
6. Hold the remaining case half through the bearing trunnion and install it on the ring gear flange half, being sure scribed mark made previously is in alignment.
7. Insert axle shafts to align side gear ring with bevel side gear, Fig. 8. If this is not done there may be some difficulty when installing axle shafts during final assembly. Tighten attaching bolts evenly to 35-45 ft-lb.
8. Check clearance between pinion mate shaft and the V of the case, Fig. 9. Do this by placing shim stock or feeler gauges on both ends of the same shaft and on opposite sides of the V. The clearance should be approximately .015".

Installation Note

Make sure the spline end of the axle shaft does not interfere with the pinion mate shafts. This can be checked with a steel tape by measuring from the bottom of the axle shaft bearing bore to the pinion mate shafts. Then measure the axle shafts from the corresponding point of the bearing to the end of the spline. The minimum clearance required is ⅛". Grind off the spline end of the axle shaft if it is too long. Check the other axle shaft in the same manner.

CAUTION: Use rear axle lubricant of the type specially recommended for locking differentials. Failure to use the proper lubricant will result in chattering of other serious malfunction.

Fig. 6 Plate clutch type of POWR-LOK differential (5 stack unit) with Belleville spring plates in center of stacks

CORVAIR TYPE

This type locking differential, Fig. 10, uses a clutch pack only on one side of the differential. Disassemble as follows:

1. Remove ring gear from differential case.
2. Chisel or punch alignment marks on case and cover, remove two flat head screws and separate case and cover.
3. Remove right-hand side gear, clutch pack preload spacer and clutch pack.

Assembly

1. Lightly oil clutch plates and side gear. Install clutch pack in differential cover in the sequence shown in Fig. 11.
2. Install side gear in clutch pack, making sure its splines engage clutch plate splines.
3. Align differential case and cover and assemble ring gear with improvised guide pins. Remove guide pins and install ring gear bolts, drawing case and cover together. Tighten bolts to 40-60 ft-lb.

Clutch Pack Preload Test

1. Clamp differential assembly in vise with soft jaws.
2. Insert a spare disassembled axle shaft yoke into one side gear. Slide a piece of 1" bar stock at least 14" long into yoke, Fig. 12.
3. With scale positioned 12" from centerline, check torque necessary to rotate yoke and side gear. Torque reading should be 50-70 ft-lb.

Fig. 7 Plate clutch type of POWR-LOK differential (5 stack unit) with Belleville spring plates at outside of stacks

FORD TYPE

Disassembly

1. Referring to Fig. 13, mark one differential bearing cap and the mating support to help position the parts properly during assembly of the carrier.
2. Remove bearing adjusting nuts and lift differential assembly out of carrier.
3. Remove differential bearings.
4. Loosen *alternate* drive gear attaching bolts evenly to release the spring pressure between differential case and cover.
5. Remove differential case cover and then the drive gear.

Fig. 8 Aligning splines of side gear and side gear ring before tightening attaching bolts

6. Remove clutch plates.
7. Remove two Belleville springs.
8. Remove clutch hub, side gear and thrust washer.
9. Drive out differential pinion shaft lock pin.
10. Drive out differential pinion shaft. Then remove pinion gears and thrust washers.

Fig. 9 Checking clearance between pinion mate shaft and V in case. Feeler gauges must be inserted on both ends of same shaft and on opposite sides of V

Fig. 10 Cross section of Corvair locking differential

Fig. 12 Checking clutch pack preload on Corvair locking differential prior to installation

Fig. 11 Exploded view of Corvair locking differential

Fig. 13 Ford locking differential

Fig. 14 NoSPIN locking differential

Assembly

1. Lubricate all parts during assembly. Referring to Fig. 13, place side gear and thrust washer in differential case.
2. With soft - faced hammer, drive pinion shaft into case only far enough to retain a pinion thrust washer and pinion gear.
3. Place a second pinion and thrust washer in position, and drive pinion shaft into place. *Carefully line up pinion shaft retainer holes.*
4. Place second pinion and thrust washer in position. Drive pinion shaft into place. Install pinion shaft retainer. *The retainer must not extend beyond the machined surface of the case.*
5. Insert two 2"x$\frac{7}{16}$" bolts through differential flange and thread them 3 or 4 turns into the drive gear as a guide in aligning drive gear bolt holes. Press or tap drive gear into position.
6. Clamp differential case in a vise. Install differential side gear on pinion gears. Place clutch hub on side gear and place thrust washer on hub.
7. Insert two $\frac{3}{16}$x2" dowel pins into differential case. Place a steel plate on differential case so that slots in dog ears straddle dowel pins. *Lubricate all differential parts so that an accurate torque check can be made.*
8. Place a bonded plate on steel plate. Make sure bonded plate inner spline teeth properly engage hub spline. Assemble remaining plates: a steel plate, a bonded plate and lastly a steel plate.
9. Place two Belleville springs on the top steel plate. Both springs are assembled with concave sides down.
10. Place differential case cover on case and start bolts.
11. Tighten bolts evenly and alternately across the diameter of drive gear. As the bolts are tightened the Belleville springs are compressed and the case and cover are pulled together.
12. Torque the bolts to 65-75 lb. ft.
13. Check torque required to rotate one side gear while the other side gear is held. Ignore the torque required to start the side gear turning. The torque required to keep it moving steadily should be between 155 and 195 lb. ft. If not within these limits, check for improper assembly.
14. Install differential in carrier.

CAUTION: Use rear axle lubricant of the type specially recommended for locking differentials. Failure to use proper lubricant will result in chattering or other serious malfunction.

Fig. 15 NoSPIN differential action when moving straight ahead

Fig. 21 Inserting assembly retaining bolt

Fig. 22 Release of spring pressure

Fig. 24 Traction equalizer cartridge

Fig. 23 Cross sectional view of Traction Equalizer differential

Fig. 25 Cutaway view of rear axle showing Traction Equalizer unit

NoSPIN DIFFERENTIAL

Fig. 14 illustrates the components of this unit while Figs. 15 through 20 show how it works.

Service Note

Before disassembling the differential case, insert a bolt through the center of the NoSPIN unit (axle shaft openings) with a flat washer on each end against the side members, Fig. 21. Thread a nut on the bolt against the flat washer finger tight. This will prevent possible injury caused by the unit flying apart due to the spring pressure within itself during disassembly of the differential case.

Disassembly

1. Remove nuts from differential case and lift out NoSPIN unit. Mount unit in a small press, Fig. 22.
2. Apply enough pressure on head of

bolt to release spring pressure against nut.
3. Remove nut and flat washer by reaching underneath the press.
4. Slowly release press and allow unit to disassemble itself until spring pressure is fully released.
5. Remove unit from press and remove parts. The center cam may be removed from the spider by expanding the snap ring with small screwdrivers or wedges. However, it is not necessary to remove the center cam from the spider even if only one part is damaged since the center cam, snap ring and spider are not serviced separately—only as an assembly.
6. Wash all parts with cleaning solvent. Inspect all mating surfaces and teeth for possible wear or damage. Replace all worn or damaged parts upon reassembly. Lubricate all parts with SAE-30 oil during reassembly.

Reassembly

1. Place side member upright and install spring on same.
2. Place spring retainer on spring with flange end toward side member.
3. Install driven clutch member on spring retainer.
4. Place spider on driven clutch member, indexing teeth of same.
5. Install other driven clutch member, spring retainer, spring and side member on spider.
6. Insert a bolt through the center of the NoSPIN unit with a flat washer against the side member, and mount unit in press, Fig. 22.
7. Compress springs by pressing on head of bolt and index splines of side members with those of driven clutch members. *Keep entire unit aligned in press to prevent it from kicking out while springs are being compressed.*
8. Compress unit until side member splines are completely indexed and flush with driven clutch member.
9. Install flat washer on bolt against side member and thread nut on bolt finger tight so it has the appearance of Fig. 21 when removed from press.

TRACTION EQUALIZER

Fig. 23 is a cross-sectional view of this device. It consists of an internally splined cartridge, Fig. 24. One end mates with the externally splined differential case extension. The shell is loaded with a series of specially treated clutch plates which are splined alternately on the inside and outside diameters to match the internal splines of the cartridge and the external splines on the lengthened axle shaft splines. A series of Belleville spring washers maintain a constant pressure on the clutch plates. Oil scoops automatically pick up the standard axle lubricant.

Operation

During a straight forward drive, the drive torque is transmitted to the wheels in the same manner as with a conventional rear axle. Likewise, straight rearward driving employs the same principles as does the conventional rear axle.

When making a turn, differential action is required in order to permit the outside wheel to travel a greater distance, and faster, than the inside wheel. While differentiation takes place within the differential case, the outer wheel ground traction overpowers the clutch pack friction, thereby causing the clutch plates to rotate. This action takes place constantly in both units mounted on the axle shafts as the vehicle deviates minutely from a straight forward or straight rearward drive.

Differential Removal

1. Remove plug from bottom of axle housing and drain lubricant.
2. Back off and remove Traction Equalizer retaining set screws from housing. Fig. 25. *If only axle shafts are to be removed, do not disturb cartridge set screws.*
3. Remove axle shaft drive nuts and washers.
4. Hold a short drift firmly against center of axle shaft flange *between raised circular lugs* and strike drift a sharp blow to loosen tapered dowels. *Do not strike raised circular lugs with hammer as the lugs are liable to shatter and explode. Do not pry shaft loose. Pry bars, chisels and wedges will damage hub, shaft, flange and oil seals.*
5. Remove dowels and pull out axle shafts.
6. If cartridge remains on differential case splines when axle shaft is removed, insert long hooked rod through housing sleeve. Hook cartridge on inside, pull off differential case splines and leave in housing.
7. Disconnect universal joint at pinion shaft.
8. Disconnect power unit (if equipped).
9. Remove carrier-to-housing stud nuts and washers, leaving the two top nuts partially screwed on studs to prevent carrier from falling.
10. Break carrier loose from housing with a rawhide mallet (remove tapered dowels where used).
11. To remove carrier from a front mounted axle, place a roller jack under carrier, remove the two top nuts and work carrier free. To remove carrier from a top mounted axle, use a chain fall and puller screws in holes provided.

Disassembly

1. Place cartridge assembly under a press with oil scoop end down. A slight press pressure on the retainer assembly in the cartridge will compress the spring and permit removal of the outer snap ring.
2. Remove snap ring. Release press pressure and remove retainer, spring and axle collar.
3. Replace cartridge under press, oil scoop end down. Insert a mandrel with flange end up. Apply a slight pressure to compress Belleville springs and remove retaining snap ring.
4. Release press pressure and remove mandrel. Invert cartridge assembly and place over a post or bar to keep internal parts in order. Hold internal parts down with a sleeve (or equivalent tool) and lift off cartridge shell.
5. Clean and inspect shell and snap ring at oil scoop end.

Inspection & Repair

1. Wire internal parts together in original order and clean in kerosene or diesel fuel oil (not gasoline). Dry immediately after cleaning, using lintless, absorbent paper towels or wiping rags free of abrasive material.
2. Replace dry internal parts on post and remove wire.
3. Remove any accumulation of grit, dirt or gum from housing bowl and sleeve. Clean housing with solvent and dry with compressed air.
4. Inspect housing for cracks, loose studs, nicks or burrs at machined surfaces. Remove nicks or burrs with a stone or file.
5. Make all necessary repairs or parts replacement before installing drive unit and cartridge in housing.

Reassembly

1. Install snap ring at oil scoop end (if removed).
2. Place cartridge shell with oil scoop end down over mandrel.
3. Starting with a thick washer and following with discs and Belleville springs, take internal parts from post, one at a time. Inspect and reoil with axle shaft lubricant, install in shell and over mandrel. *Discs are to be installed alternately starting with an externally splined disc. Belleville springs are to be installed in alternating groups of four starting with concave side down toward last disc which is to be an externally splined disc. If discs bind in cartridge, tap into position with a screwdriver; do not force down as they will be cocked.*
4. Carefully remove mandrel, being careful not to misalign splines, and insert mandrel at top of cartridge with flange end up.
5. Place cartridge under press and apply a slight pressure to compress Belleville springs and install snap ring.
6. Release press pressure and mount a dial indicator so that its stem is against the top of the mandrel flange.
7. Apply a slight pressure and read dial indicator for movement required to compress discs and springs. Compression should be .120″ to .160″. If compression is more than desired, add one or more splined discs, being sure last disc is externally splined. (Discs are about .040″ thick.)
8. Release press pressure and remove mandrel. Install axle shaft collar, spring and retainer with chamfered edge of collar up.
9. Compress spring with slight pressure and install snap ring.
10. Insert axle shafts in housing and carefully mount cartridges on splined ends of shafts through housing bowl opening. Withdraw shafts and cartridges from housing just enough to

allow clearance for carrier installation.
11. Install carrier in housing.
12. Complete assembly of one axle shaft in housing. Engage shaft with splines in side gear. Install taper dowels, lockwashers and nuts. Restrain pinion shaft and rotate hub or wheel until cartridge engages splines on differential case. Install other axle shaft in same manner.
13. Install housing drain plug and insert lubricant.
14. Insert cartridge retaining set screw and jam nut to prevent loss of lubricant.
15. Drive vehicle in a circle to permit second cartridge to engage splines on differential case.
16. Turn each cartridge set screw until it touches spring retainer, then back off screw 1½ to 2 turns and tighten jam nut to 30-35 ft. lbs.

EATON DRIVING AXLES

LUBRICANT CAPACITIES

Lubricant capacities are given as a guide only. The capacities of two similar axles in the same series may vary considerably due to design changes and the vehicle manufacturers' installation. The actual service capacity may be determined by carefully measuring the amount of lubricant necessary to fill the assembly to the correct level and measuring the lubricant again when it is drained. The vehicle should be on a level floor when this inspection is made.

Axle Adjustments

PROCEDURE

Measuring ring gear to drive pinion backlash and checking tooth contact pattern before disassembly, plus "punch marking" components for related position are recommended procedures for easier adjustment of axle after reassembly. If major axle parts are replaced, these identifying marks and reference measurements may not necessarily provide correct adjustment. However, usual return of parts to the identifying marks will serve as a reference to position parts as near as possible to correct adjustment.

The following is an outline of axle adjustment procedure and includes information on when adjustment should be performed and references to detailed instructions:

1. *Power Divider Input and Output Shaft Bearing Clearances.* These adjustments are made during reassembly of power divider. Refer to individual axle instructions.
2. *Drive Pinion Bearing Preload.* This adjustment is made before installing drive pinion (see below).
3. *Drive Pinion Position Adjustment.* Initial or preliminary adjustment is made during reassembly (see below).
4. *Differential Bearing Preload.* This adjustment is made in combination with ring gear and drive pinion adjustments (see below).
5. *Ring Gear and Drive Pinion Backlash.* Adjustments are given below.
6. *Ring Gear Tooth Contact.* Check ring gear tooth contact when adjusting ring gear and drive pinion (see below).
7. *Ring Gear Thrust Block Clearance.* This adjustment is made after drive pinion adjustments are completed and before differential carrier is installed in axle housing. Refer to individual axle instructions.
8. *Wheel Bearing Adjustments.* Procedure is given below.

		Dimensions for Drive Pinion Bearing Preload Adjustment		Dimensions for Drive Pinion Position Adjustment

* spacer not used on all model 13802 axles. † spacer not used on all model 3802 axles.

Fig. 1 Eaton axle drive pinion adjustment specifications

Fig. 4 Checking drive pinion bearing preload with spring scale (pinion in press)

Fig. 2 Checking drive pinion bearing preload with torque wrench (pinion in vise)

Fig. 3 Checking drive pinion bearing preload with spring scale for Tandem Drive Axles (pinion in vise)

The ring gear tooth contact patterns illustrated are approximate shapes. Actual contact may vary, however the same general shape should be obtained. When adjusting gear sets that have been in service, tooth contact may vary because of wear. To obtain best results, strive to obtain a pattern coinciding with original patterns.

Pattern "A"
CORRECT TOOTH CONTACT

Correct adjustment is obtained when pattern of tooth bearing *(both lengthwise and profile)* appear as shown.

Pattern "A"

Pattern "B"
CONCENTRATED BEARING AT TOE

Not enough backlash . . . move ring gear *away* from drive pinion to increase lengthwise bearing. This may change the profile bearing to some extent and an adjustment of the pinion may be required.

Pattern "C"
CONCENTRATED BEARING AT HEEL

Too much backlash . . . move ring gear *toward* drive pinion to obtain correct lengthwise bearing. This may change the profile bearing to some extent and an adjustment of the pinion may be required.

Pattern "D"
PROFILE BEARING HIGH

Pinion is out too far . . . remove shims to move drive pinion toward ring gear. Then move ring gear away from pinion to obtain correct lengthwise bearing.

Pattern "E"
PROFILE BEARING LOW

Pinion is in too far . . . add shims to move drive pinion away from ring gear. Then move ring gear toward pinion to obtain correct lengthwise bearing.

Fig. 5 Correct and incorrect tooth contact patterns for all models except 22M, 28M, 36M Tandem Axles

DRIVE PINION BEARING PRELOAD

If the original pinion spacer can be used in reassembly, this should provide a close to correct adjustment of pinion bearing preload. If original spacer cannot be used start with spacer thickness recommended in Fig. 1.

With drive pinion, bearings, bearing cage and other related parts (oil seal and retainer removed) assembled and lubricated, measure and adjust pinion bearing preload.

Torque Wrench Method

1. Mount an adapter on pinion bearing cage, Fig. 2.
2. Hold drive pinion in a vise or arbor press. If an arbor press is used, apply approximately 5 tons pressure to bearings.
3. Rotate bearing cage by hand several revolutions to assure normal bearing contact. Then rotate bearing cage with a torque wrench and note torque reading as cage is rotated.
4. Correct bearing preload is indicated by a torque of 15 to 35 inch lbs. If

The ring gear tooth contact patterns illustrated are approximate shapes. Actual contact may vary, however the same general shape should be obtained. When adjusting gear sets that have been in service, tooth contact may vary because of wear. To obtain best results, strive to obtain a pattern coinciding with original patterns.

Pattern "A"
CORRECT TOOTH CONTACT

Correct adjustment is obtained when pattern of tooth bearing *(both lengthwise and profile)* appear as shown.

Pattern "A"

Pattern "B"
CONCENTRATED BEARING AT TOE

Not enough backlash . . . move ring gear *away* from drive pinion to increase lengthwise bearing. This may change the profile bearing to some extent and an adjustment of the pinion may be required.

Pattern "C"
CONCENTRATED BEARING AT HEEL

Too much backlash . . . move ring gear *toward* drive pinion to obtain correct lengthwise bearing. This may change the profile bearing to some extent and an adjustment of the pinion may be required.

Pattern "D"
PROFILE BEARING HIGH

Pinion is out too far . . . remove shims to move drive pinion toward ring gear. Then move ring gear away from pinion to obtain correct lengthwise bearing.

Pattern "E"
PROFILE BEARING LOW

Pinion is in too far . . . add shims to move drive pinion away from ring gear. Then move ring gear toward pinion to obtain correct lengthwise bearing.

Fig. 6 Correct and incorrect tooth contact pattern for Tandem Axle Models 22MF, 22MR, 28MF, 28MR, 36MF, 36MR

incorrect, adjust by changing pinion bearing spacer. Use a thicker spacer to decrease preload or a thinner one to increase preload. *Do not use shim stock to increase thickness of spacer; always use correct size spacer.*

Spring Scale Method

1. Wrap a soft wire around bearing cage, Figs. 3 and 4.
2. Hold drive pinion in a vise or arbor press. If a press is used, apply approximately 5 tons pressure to bearings.
3. Pull scale on a line tangent to the cage outside diameter as shown with the scale attached to the wire and note scale reading.
4. To calculate torque from scale reading, measure cage radius (see Fig. 1). Then multiply radius times scale reading. Example: With cage radius 2½" and scale pull 12 lbs., torque would be 12 x 2½ or 30 in. lbs.
5. Correct bearing preload is indicated by a torque of 15 to 35 inch lbs. If incorrect, use a thicker spacer to decrease preload and a thinner one to increase preload. *Do not use shim stock to increase thickness of spacer; always use correct size spacer.*

Ring Gear Tooth Nomenclature

check tooth contact pattern

Tooth contact pattern consists of the lengthwise bearing and profile bearing. The lengthwise bearing is the bearing along the tooth of the ring gear. The profile bearing is the bearing up and down the tooth (See fig. 206). In determining correct ring gear tooth contact, these two types of bearings must be considered separately to obtain proper results in combination.

With differential bearings adjusted correctly, paint at least ten ring gear teeth with red lead or prussian blue. Turn ring gear by hand a few revolutions in both directions to obtain impressions (or patterns) of tooth contact. Compare contact patterns with those shown in figure 208 or 209. If tooth contact patterns are not correct, move ring gear and/or drive pinion as necessary to adjust for correct pattern. Keep in mind that ring gear movement affects lengthwise bearing and that drive pinion movement affects the profile bearing.

Adjust to obtain correct tooth contact on drive side of teeth. Under this condition, the coast side tooth contact is usually satisfactory.

Fig. 7 Ring gear and drive pinion movement to obtain correct tooth contact pattern

DRIVE PINION POSITION

Drive pinion position in relation to ring gear is adjusted by adding or removing shims between pinion bearing cage and differential carrier or power divider case.

To assist in adjustment of ring gear and pinion, pinion should be positioned as near as possible to the correct position during reassembly. This can be accomplished as follows:

If the original ring gear and pinion are used in reassembly, use same size and quantity of shims removed during disassembly. If a new ring gear and pinion are used in reassembly, use shim pack recommended in Fig. 1.

The drive pinion position may also be set with a depth gauge. Fig. 1 also shows the basic dimensions used for gauge setting.

Fig. 8 Measuring ring gear backlash with dial indicator

RING GEAR & DRIVE PINION

Except Model 42M Tandem

1. With differential bearings lubricated and bearing cap screws tightened *finger tight,* adjust ring gear and pinion as follows, referring to Figs. 5 and 6 for tooth contact pattern identification. Also refer to Fig. 7 for tooth nomenclature. *Note: Adjustment of bearing adjusters to change ring gear position is affected by the relative mounting positions of the ring gear and drive pinion. The following instructions are for axles with ring gear on left-hand side of drive pinion. Left and right-hand instructions in parentheses (left-hand) (right-hand) are for axles with ring gear on right-hand side of drive pinion.*
2. Tighten differential bearing adjusters to correctly seat bearing cups.
3. Loosen right-hand (or left-hand) bearing adjuster until it is very loose. Tighten left-hand (or right-hand) bearing adjuster until backlash is removed between ring gear and drive pinion. Tightening left-hand (or right-hand) adjuster moves ring gear toward drive pinion.
4. Tighten right-hand (or left-hand) bearing adjuster until snug, then continue to tighten adjuster two additional notches. This will normally position ring gear within the specified .006 to .016″ backlash. This adjustment will also preload differential bearings. Tightening right-hand (or left-hand) adjuster moves ring gear away from drive pinion.
5. Tighten differential bearing capscrews to correct torque, then measure ring gear movement with a dial indicator, Fig. 8, to determine specific backlash.
6. Paint ring gear teeth and check tooth contact pattern. Compare pattern with those illustrated in Figs. 5 and 6. If contact pattern similar to "A" is obtained, adjustment is correct.
7. If Pattern "B" is indicated, loosen left-hand (or right-hand) bearing adjuster and tighten right-hand (or left-hand) bearing adjuster equal amounts. Recheck tooth contact pattern. If pattern is not corrected, continue to move bearing adjusters (the same number of notches) until proper lengthwise pattern is obtained.
8. If Pattern "C" is indicated, loosen right-hand (or left-hand) bearing adjuster and tighten left-hand (or right-hand) adjuster equal amounts. Recheck tooth pattern. If pattern is not corrected, continue to turn bearing adjuster equal amounts until proper lengthwise bearing pattern is obtained.
9. If Patterns "D" or "E" is indicated, adjustment of drive pinion position is necessary. Add or remove pinion bearing cage shims to move drive pinion as pattern indicates. When drive pinion position is changed, the adjustment may affect lengthwise bearing. If necessary, readjust backlash for proper lengthwise bearing. Recheck tooth contact pattern.
10. When correct tooth pattern "A" is obtained, install adjuster locks and cotter pins. Lockwire differential bearing capscrews.

Model 42M Tandem Axle

For easier adjustment, it is recommended that the differential assembly and power divider assembly be removed from the differential carrier. In the following instructions, it is assumed that only the countershaft assembly and bearings are installed in differential carrier. Refer to Fig. 5 for tooth contact pattern and Fig. 7 for tooth nomenclature.

1. To adjust countershaft bearings, turn left-hand bearing adjuster until two or three threads are engaged. Tighten right-hand bearing cage

until end play is removed from countershaft bearings.

2. To preload countershaft bearings, continue to tighten right-hand bearing cage until resistance is felt when rotating countershaft. *This preload adjustment can be maintained during ring gear adjustment by turning bearing adjuster and cage equal amounts. Preload should be 10 to 22 inch lbs.*
3. Install power divider assembly.
4. To adjust ring gear backlash, loosen right-hand bearing cage and tighten left-hand bearing adjuster (the same number of turns) until .006 to .016″ backlash is obtained. Measure backlash with dial indicator, Fig. 8.
5. Paint ring gear teeth and check tooth contact pattern. Compare pattern with those shown in Fig. 5.
6. If Pattern "B" is indicated, loosen left-hand bearing adjuster and tighten right-hand bearing cage equal amounts. Recheck tooth pattern. If pattern is not corrected, continue to move bearing cage and adjuster (the same number of notches) until proper lengthwise bearing pattern is obtained.
7. If Pattern "C" is indicated, loosen right-hand bearing cage and tighten left-hand bearing adjuster equal amounts. Recheck tooth pattern. If pattern is not corrected, continue to turn bearing cage and adjuster equal amounts until proper lengthwise bearing pattern is obtained.
8. If Pattern "D" or "E" is indicated, adjustment of drive pinion is necessary. Add or remove pinion bearing cage shims to move drive pinion as pattern indicates. When drive pinion position is changed, the adjustment may affect lengthwise bearing. If necessary, readjust backlash for proper lengthwise bearing. Recheck tooth contact pattern.
9. When Pattern "A" is obtained, install countershaft bearing covers, gaskets and capscrews. Install differential assembly.

WHEEL BEARING ADJUSTMENT

Wheel bearings should be adjusted to provide .001 to .010″ end play.

1. Remove outer nut and lockwasher.
2. While turning wheel in both directions, tighten inner nut until a slight bind on nut is present.
3. Back off inner nut 1/3 turn to permit wheel to rotate freely.
4. Install lockwasher and outer nut, and lock both nuts in this position.

Eaton Single Reduction Axles

DISASSEMBLE

Differential Carrier, Fig. 9

1. Drain lubricant.
2. Disconnect propeller shaft and remove axle shafts.
3. Unfasten and remove differential carrier from axle housing and discard gasket.
4. Unscrew pipe plug, then remove spring and oil distributor (if used).
5. Remove ring gear thrust block from end of adjusting screw after removing locknut and screw (if used).
6. Punch mark differential bearing caps and carrier for correct location on reassembly. Also punch mark differential bearing adjusters for correct location of adjuster locks.
7. Remove differential bearing caps and adjusters. Tilt ring gear away from pinion and lift out differential assembly.
8. Remove pinion bearing cage-to-carrier capscrews. Drive pinion assembly out of carrier, being careful not to allow assembly to fall on flange. *Note size and quantity of shims under bearing cage flange for easier adjustment during reassembly.*

Drive Pinion

1. Hold companion flange in vise, then remove cotter pin, nut and flat washer.
2. Drive pinion out of flange.
3. Remove pinion bearings cage assembly. Remove oil seal retainer, flange flat washer (if used) and outer bearing cone from cage. Discard bearing cage cork seal.
4. If replacement is necessary, remove bearing cups from cage, using suitable puller. Remove oil seal and felt seal from seal retainer.
5. Remove bearing spacer washer (if used) and spacer from pinion.
6. Remove inner bearing cone and pilot bearing from pinion, using suitable pullers.

Fig. 2. Exploded View of Single Reduction Axle Differential Carrier

RH — Right-hand LH — Left-hand

Fig. 9 Disassembled view of Eaton Single Reduction Axle Differential Carrier

Fig. 10 Disassembled view of differential

Fig. 11 Disassembled view of drive pinion. Companion flange flat washers and pinion bearing spacer washers are not used on all axles

Differential

1. Punch mark differential cases for correct location in reassembly. Separate case halves and lift off plain half.
2. Lift out differential spider, pinions and thrust washers.
3. Remove bearing cones from differential cases with a split-type puller.
4. To remove ring gear from flanged differential, drill off the flat head of rivets (on ring gear side) and drive out rivets. Some ring gears are fastened with bolts and locknuts.

REASSEMBLE

Differential, Fig. 10

1. Rivet (cold) ring gear to flanged differential case, using a press. Compress rivets from 44 to 48 tons on Model 1315 and from 47-50 on all other models. If bolts and locknuts are used, tighten to correct torque. Lubricate internal parts of differential during reassembly.
2. Press bearing cones on differential cases.
3. Assemble spider, pinions and thrust washers in flanged differential case. Then tap plain differential case into place, aligning punch marks made during disassembly. Install capscrews, bolts and nuts. Tighten nuts and capscrews to correct torque and lockwire capscrews and nuts.

Drive Pinion, Fig. 11

1. Press pilot bearing on drive pinion and stake in four places as shown in Fig. 12.

Fig. 12 Staking drive pinion pilot bearing (stake in four places)

2. Press inner bearing cone on pinion. Place spacer and washer (if used) on pinion.
3. If removed, press bearing cups into pinion bearing cage. Install new felt seal and oil seal in oil seal retainer.
4. Lubricate drive pinion bearings, then place pinion bearing cage and outer bearing cone on drive pinion. *Do not install oil seal retainer until pinion bearing adjustment is completed.*
5. Temporarily assemble companion flange to pinion as follows: Place companion flange flat washer (if used) on drive pinion. Press flange on pinion. Install and tighten pinion nut to correct torque. Rotate pinion bearing cage while tightening nut. Check pinion bearing preload adjustment as outlined previously.
6. With pinion bearings correctly adjusted, remove companion flange. Install new cork seal in groove of pinion bearing cage. Install oil seal retainer, then reinstall companion flange, flat washer and pinion nut. Tighten nut to correct torque and install cotter pin.

Differential Carrier

1. Install same quantity and size shims

that were removed in disassembly on pinion bearing cage, then install drive pinion assembly in carrier. Install and tighten capscrews to correct torque.

2. Thread thrust block adjusting screw (if used) far enough into carrier to mount thrust block. Lubricate and install thrust block on end of adjusting screw.
3. Place differential assembly in carrier and install differential bearing cups, adjusters and caps. Install and finger tighten differential bearing capscrews. Tighten adjusters to correctly seat differential bearings. Adjust ring gear and drive pinion as outlined previously.
4. With ring gear and pinion correctly adjusted, and differential bearing capscrews tightened to correct torque, install cotter pins to secure adjuster locks. Lock wire capscrews.
5. Install oil distributor (if used), spring and pipe plug.
6. Adjust thrust block clearance as follows: Tighten adjusting screw to position thrust block against ring gear. Loosen adjusting screw 1/8-1/4 turn to obtain .010 to .015" clearance between thrust block and ring gear. Tighten locknut. Bend ear of lock against nut to secure adjustment.

Install Carrier in Housing

1. Using a new gasket, install carrier in axle housing. Install capscrews and tighten to correct torque.
2. Install axle shaft and connect propeller shaft. Fill housing with correct lubricant.

Eaton Two Speed Axles

Fig. 13 Cutaway view of Eaton Two Speed Axle assembly

Fig. 14 Sliding clutch gear position for high axle ratio

Fig. 15 Sliding clutch gear position for low axle ratio

DISASSEMBLE

Differential Carrier, Fig. 16

1. Place axle in low range. Remove shift unit nuts and washers. Disconnect electric wires, air tubing or vacuum tubing as necessary to remove shift unit.
2. Drain lubricant. Disconnect propeller shaft and remove axle shafts. Unfasten and lift differential carrier from axle housing. Discard carrier gasket.
3. Unscrew pipe plug and remove spring and oil distributor.
4. Remove seal and spring from shift fork. Remove expansion plugs and drive out shift fork shaft. Disengage and remove shift fork.
5. Remove sliding clutch gear. *If preliminary inspection reveals that ring gear and drive pinion are satisfactory, check backlash and tooth pattern for easier adjustment in reassembly.*

RH — Right-hand LH — Left-hand

Right and Left Hand is determined by standing at rear of vehicle and facing rear of axle (as installed in vehicle.)

Fig. 17 Disassembled view of differential assembly

6. Punch mark right-hand differential bearing adjuster for location of lock in reassembly. Cut lockwire and remove differential bearing cap screws. Remove right-hand differential bearing cap, bearing adjuster and lock.
7. Cut lockwire and remove left-hand differential bearing cap, bearing adjuster and lock as an assembly to assure correct position of ring gear during reassembly.
8. Tilt up planetary end of differential, then lift out differential assembly.
9. Remove pinion bearing cage-to-differential carrier capscrews. Then drive pinion assembly out of carrier, being careful not to allow assembly to fall on flange. *Note size and quantity of shims on bearing cage flange* for easier adjustment in reassembly.

Drive Pinion

1. Hold companion flange in vise and, after removing cotter pin, nut and flat washer, drive pinion out of flange.
2. Remove pinion bearing cage assembly, oil seal retainer assembly (flanged or pressed-in type) flange flat washer (if used) and outer bearing cone from pinion bearing cage.
3. Discard pinion bearing cage cork seal (used only with flanged type oil seal retainer).
4. Remove oil seal and felt seal from oil seal retainer. If replacement is necessary, remove bearing cups from cage, using suitable puller.
5. Remove pinion bearing spacer washer (if used) and spacer from drive pinion.
6. Remove inner bearing cone and pilot bearing, using pullers.

Differential

1. Remove locknuts and bolts holding gear support cases together. Tap alternately on opposite sides of ring gear with a soft-faced hammer until ring gear is free of flange on support case.
2. Lift off left-hand support case, oil collector drum and thrust washer.
3. Lift off ring gear.
4. Pry off high-speed clutch plate, then remove idler pinions and pins.
5. Lift out differential assembly. Remove support case thrust washer.
6. Punch mark differential cases for correct location in reassembly. Cut lockwires and remove capscrews, then lift off right-hand differential case.
7. Lift out long-hub side gear and thrust washer.
8. Lift out spider, pinions and thrust washers. Remove short-hub side gear and thrust washer from left-hand differential case.
9. To remove differential bearing cones, place pilot punch in holes provided in gear case support. Tap on bearing cone inner race, alternately through each hole until cone is removed. Remove bearing cones from both support cases in the same manner.

REASSEMBLE

Differential, Fig. 17

1. Press bearing cones on gear support case.
2. Place thrust washer and short-hub side gear in left-hand differential case. Assemble side pinions and thrust washers to spider, then place this assembly in left-hand differential case.
3. Place long-hub side gear with thrust washer on side pinions. Place right-hand differential case over differential gears, aligning punch marks on both cases. Then install capscrews and tighten to correct torque. Lockwire capscrews.
4. Place right-hand support case thrust washer and differential assembly in right-hand support case. Install spider and pinions. Place high speed clutch plate on idler pinions. *Make certain that chamfered teeth of clutch plate are positioned toward idler pinions.*
5. Mount ring gear, oil collector drum, thrust washer and left-hand support case on right-hand support case. *During assembly of these parts, temporarily place two bolts in mounting holes. This procedure will assure bolt hole alignment as these parts are assembled into final position. Secure assembly with bolts and locknuts. Temporarily install sliding clutch gear and rotate idler pinions to make sure parts are assembled correctly. Tighten locknuts to correct torque.*

Drive Pinion, Fig. 18

1. Press pinion pilot bearing on drive pinion, then stake in place as shown in Fig. 12.
2. Press inner bearing cone on drive pinion.
3. If removed, press bearing cups in bearing cage.
4. Install new felt seal and oil seal in retainer.
5. Lubricate drive pinion bearings. Place pinion bearing spacer, spacer washer (if used), bearing cage and outer bearing cone on drive pinion. *Do not install oil seal retainer until pinion bearing adjustment is completed.*
6. Temporarily assemble companion flange as follows: Place flange flat washer (if used) on drive pinion. Press flange on pinion and install flat washer and pinion nut, tightening nut to correct torque. *Rotate bearing cage while tightening pinion nut.* Check pinion bearing preload adjustment as outlined previously.
7. To install oil seal retainer assembly (after drive pinion bearings are cor-

Fig. 18 Disassembled view of drive pinion. Companion flange flat washers and pinion bearing spacer washers are not used on all axles

rectly adjusted) remove nut, flat washer and companion flange. Install oil seal retainer assembly *(pressed-in type mounts in recess of bearing cage with flat washer positioned between cage recess and oil seal retainer. Flanged-type is attached with same capscrews that fasten bearing cage)*. Install companion flange, flat washer and nut, tightening nut to correct torque.

Differential Carrier

1. Using same quantity and size of shims that were removed during disassembly on pinion bearing cage flange, install drive pinion assembly in carrier. Install bearing cage capscrews and lockwashers, tightening capscrews to correct torque. Lubricate differential bearings during reassembly.
2. Place differential assembly in carrier and install differential bearing cups. Install assembled left-hand differential bearing cap, adjuster and lock. Install right-hand differential bearing cap and adjuster. Install and finger tighten differential bearing capscrews. Tighten right-hand bearing adjuster to seat differential bearings. Adjust ring gear and drive pinion as outlined previously.
3. With ring gear and drive pinion correctly adjusted, tighten differential bearing cap screws to correct torque. Then install cotter pins to secure locks and lockwire capscrews.
4. Install sliding clutch gear.
5. Install and engage shift fork with sliding clutch gear. Install shift fork shaft and expansion plugs.
6. Place seal on shift fork with bottom hole (stamped on seal) over lower stud. Install spring on seal.
7. Install oil distributor, spring and pipe plug in carrier.

Install Carrier In Housing

1. Using a new gasket, install differential carrier in axle housing. Install and tighten capscrews to correct torque. Install axle shafts and connect propeller shaft. Fill housing with correct lubricant.
2. Install electric shift unit or air-torsion spring unit on carrier, engaging swivel with slot in shift fork shaft. Install mounting nuts and washers. For electric shift, connect electric wires. For air-torsion spring shift, connect air line to unit.

Eaton Planetary Double Reduction Axles

This axle assembly, Fig. 19, is designed to provide a compact unit with heavy-duty load capacity. This is accomplished by incorporating a rugged ring gear and drive pinion set and a durable planetary unit in a single axle housing.

Differential Carrier Service

Remove the differential carrier from the axle housing as outlined for the two speed axle. Procedures for disassembly are the same as for the two speed axle. However, the Planetary Double Reduction Axle does not use a shift mechanism.

A sun gear is used in place of the sliding clutch gear. To remove the sun gear, remove the retainer which holds the sun gear in position, then remove sun gear.

Fig. 19 Power flow through Planetary Double Reduction Axle. This unit is similar to the two speed type but it does not have a shift unit

Eaton "D" Series Tandem Drive Axles

The Series "D" driving unit consists of two axles coupled by a power divider. Three different combinations are available:

1. A single reduction forward axle with power divider, and a single reduction rearward axle.
2. A two-speed forward axle with power divider, and a two-speed rearward axle.
3. A planetary double reduction forward axle with power divider, and a planetary double reduction rearward axle.

DISASSEMBLE

It is recommended, but not necessary, that the axle housing cover be removed to replace the differential carrier and power divider assembly.

1. Drain lubricant, disconnect propeller shafts at companion flanges and remove axle shafts.
2. Remove companion flange from output shaft.
3. Remove axle housing cover and discard gasket.
4. To disassemble axle housing cover, remove oil seal from output shaft opening, using a suitable puller. Remove snap ring from output shaft opening, then press rear bearing from axle housing cover. *Rear bearing sleeve is mounted on output shaft.*
5. Disconnect lockout shift lever connections.
6. If axle is "Two-Speed", remove shift units, referring to "Two-Speed Axle" Section.
7. After removing stud nuts and lockwashers, lift and pull differential carrier and power divider out of axle housing.

Carrier & Power Divider, Figs. 20, 21, 22

1. If preliminary inspection reveals that ring gear and drive pinion are satisfactory, check backlash and tooth contact pattern for easier adjustment in reassembly.
2. Remove carrier cover from carrier.
3. Lift inter-axle differential off output shaft side gear.
4. Before disassembling inter-axle differential, punch mark cases for correct position during reassembly. Cut lockwire and remove nuts and bolts. Separate cases and remove thrust washers, side pinions, bushings and spider.

Output Shaft

1. Drive output shaft from differential carrier, driving at companion flange end of shaft.
2. To disassemble output shaft, remove snap ring, then lift off side gear assembly. Discard output shaft "O" rings. If replacement is necessary, remove bushing from bore of output shaft.

Fig. 20 Power flow through Single Reduction "D" Series Tandem Drive Axle

3. To remove output shaft front bearing from side gear, place side gear assembly in press with split-type puller plates under front bearing, then press side gear out of front bearing.

Input Shaft

1. Remove snap ring from input shaft, then lift off helical side gear, thrust washer and "D" washer. If replacement is necessary, press bushings from bore of side gear.
2. Remove companion flange from input shaft.
3. Remove input shaft bearing cover and shims. *Note size and quantity of shims for easier adjustment during reassembly.* Remove oil seal and felt seal from bearing cover.
4. Drive input shaft out of differential carrier cover.

Fig. 24 Disassembled view of "D" Series drive pinion

5. To remove bearing from input shaft, place assembly in a press with threaded end of input shaft upward. Then press input shaft out of bearing.

Lockout Mechanism (Vacuum Type)

Either vacuum-operated or air-operated lockout may be used on "D" Series Axles. The air-operated type is covered further on. The following instructions are for the vacuum-operated lockout.

1. Pull boot off lockout shift lever. Remove clevis pin and remove shift lever.
2. Referring to Fig. 23, remove shift lever bracket. Compress compression spring, then remove pin, retainer washer and compression spring from shift fork and push rod.

Fig. 23 Vacuum-operated lockout details

cage capscrews are accessible to permit removal of pinion with flange assembled.

(b) The drive pinion for "D" Series Tandem Axles are equipped with a helical gear, Fig. 24, which must be removed to gain access to pinion bearing cage capscrews. Therefore, to remove drive pinion, remove nut previously loosened before differential removal.

(c) Mount bearing puller on helical gear, gripping gear with puller legs and placing puller screw against pinion. Then pull gear off pinion. Remove capscrews from bearing cage and then remove drive pinion assembly.

REASSEMBLE

Fig. 25 Disassembled view of output shaft and axle housing cover parts

3. Lift input shaft sliding clutch and shift fork and push rod assembly from differential carrier cover.

Final Disassembly

1. Before removing differential assembly, remove cotter pin and loosen drive pinion helical gear nut.
2. Be sure to remove pipe plug, spring and oil distributor from differential carrier before attempting to remove differential assembly. *Refer to separate sections of this chapter for instructions covering the three types of axles used with the "D" Series combination.*
3. Removing and disassembling the drive pinion is covered in the separate sections of this chapter for the three axle types used, with the following variations:

(a) The drive pinions for the individual axles are equipped with companion flanges. For this type installation, the pinion bearing

Drive Pinion

Refer to separate sections of this chapter for instructions covering the three types of axles except for the following variation:

The drive pinions for the standard axle units are equipped with companion flanges. The pinion bearing cage capscrews are accessible to permit installation of pinion with companion flange installed.

The drive pinion for the "D" Series

Fig. 26 Disassembled view of inter-axle differential

Fig. 27 Disassembled view of vacuum-operated lockout mechanism

Tandem Axle units are equipped with a helical gear, Fig. 24, and the bearing cage capscrews cannot be installed with the helical gear attached to the drive pinion. Install the pinion in these axles with the helical gear removed. After pinion is installed, place helical gear on pinion. Install and tighten pinion nut to correct torque, then install cotter pin.

With drive pinion and differential assembled in differential carrier and correctly adjusted, install power divider components as follows:

Output Shaft

1. If removed, press bushing in bore of output shaft.
2. Press front bearing on output shaft side gear. Place side gear assembly on output shaft and install snap ring.
3. Install two "0" rings in grooves of output shaft.
4. Lubricate output shaft "0" rings, front bearing and bushing, then install output shaft assembly in differential carrier by tapping front bearing into bearing bore of carrier.

Inter-Axle Differential, Fig. 26

1. Install bushings, side pinions and thrust washers on journals of differential spider. Lubricate all parts during reassembly.
2. Place spider assembly in male differential case. Install female case, aligning punch marks made during disassembly, and secure with bolts and nuts. Tighten nuts to correct torque and install lockwire.
3. Place inter-axle differential on output shaft side gear. Position differential with nuts away from output shaft side gear.

Lockout Mechanism (Vacuum Type), Fig. 27

Instructions for the air-operated type lockout is covered further on.

1. Install felt seal and seal retainer in recess in carrier cover. Engage lockout shift fork with groove in input shaft sliding clutch. Place this assembly in differential carrier cover.
2. Place compression spring and retainer washer on push rod, depress spring and install retainer washer pin. Coat spring and retainer washer with grease.
3. Install new gasket and shift lever bracket on differential carrier cover and install capscrews and lockwashers. Tighten screws to correct torque. If removed, install grease fitting in bracket.
4. Place lockout shift lever in bracket, engaging slot in push rod. Install clevis pin and cotter pin.
5. Place boot over shift lever and secure boot to bracket.

Input Shaft, Fig. 28

1. Press bearing on threaded end of input shaft.
2. Place input shaft assembly in differential carrier cover, engaging sliding clutch.
3. Install felt seal and oil seal in input shaft bearing cover. Using same size and quantity of shims removed during disassembly, install shims and bearing cover on carrier cover. Install capscrews finger tight, with lockwashers. *To check bearing adjustment or determine thickness of shims required, install bearing cover on carrier cover without shims. Install and tighten capscrews finger tight. Then, using a feeler gauge, measure clearance between bearing cover and carrier cover. This clearance measurement plus .003" would equal the thickness of shims required for correct bearing clearance.*
4. Install input companion flange and nut on input shaft. Tighten nut to correct torque and install cotter pin. Tighten input shaft bearing cover capscrews to correct torque.
5. If removed, press two bushings in bore of helical side gear. Place "D" washer, thrust washer and helical side gear assembly on input shaft. Install snap ring on input shaft to secure these parts.

Differential Carrier Cover

1. Place new cover gasket on differential carrier.
2. Place carrier cover on differential carrier, aligning dowel pins with holes in cover. *During reassembly of cover to carrier, slowly rotate input shaft to engage its splines with splines in bore of inter-axle differential spider.*
3. Carefully install two cover capscrews, watching for possible bind-

Fig. 28 Disassembled view of input shaft

ing between cover and carrier. If cover assembles to carrier without bind, install remaining capscrews and tighten to correct torque.

4. After cover is assembled to carrier, check operation of inter-axle differential. Hold output shaft stationary and rotate input shaft companion flange. If the assembly differentiates, the unit is correctly assembled.

Carrier & Power Divider

1. Place new gasket on carrier. Install carrier and power divider assembly into axle housing. Install and tighten stud nuts to correct torque.
2. Assemble axle housing cover, Fig. 25, as follows: Press output shaft rear bearing in cover. Install snap ring to secure bearing. Press oil seal in same opening in axle housing cover.
3. Place new gasket on axle housing and install axle housing cover, taking care not to damage oil seal. Install stud nuts and lockwashers and tighten nuts to correct torque.
4. Install rear bearing sleeve in output shaft. Install retainer washer, output companion flange, flat washer and nut. Tighten nut to correct torque and install cotter pin.
5. Install axle shafts and fill axle with correct lubricant. Connect propeller shafts. On Two-Speed Axles, install shift units. Make lockout shift lever connections.

Eaton "M" Series Tandem Drive Axles

Fig. 29 Power flow through M Series Tandem Drive Axles

This series of axles consist of two axle units coupled by a single propeller shaft and a power divider unit. The forward rear axle on Models 22M, 28M, 32M and 36M are single reduction units combined with a power divider. The rearward rear axle is also a single reduction unit similar to the standard Eaton Single Reduction Axle, Fig. 29.

Model 42M consists of three units: Two knee-mounted double reduction axle units and a power divider. The power divider is mounted on the forward rear axle. An inter-axle propeller shaft connects the rearward rear axle to the power divider.

MODELS 22M, 28M, 32M, 36M

Note: Inasmuch as the rearward rear axle is similar to the standard Eaton Single Reduction Axle, refer to that section of this chapter for service procedures. The following material covers the procedures on the forward rear axle.

DISASSEMBLE

Carrier & Power Divider

1. Drain lubricant. Disconnect propeller shafts and remove axle shafts.
2. Disconnect lockout shift lever.
3. Unfasten and remove differential carrier and power divider assembly from axle housing.
4. If preliminary inspection reveals that ring gear and drive pinion are satisfactory, check backlash with dial indicator and take a tooth contact pattern for reference and easier adjustment in reassembly.
5. Remove pinion bearing cage cover. Remove and discard cork seal. Hold input and output companion flanges and loosen (but do not remove) pinion nut.
6. Hold input companion flange and loosen (but do not remove) flange nut.
7. Hold output companion flange and loosen (but do not remove) flange nut.
8. Punch mark differential bearing caps and carrier for correct location in reassembly. Also punch mark differential bearing adjusters for correct location of adjuster locks, Fig. 30.
9. Cut lockwires and remove differential bearing cap screws, caps, adjusters, locks and bearing cups from both sides of differential.
10. On Models 22M, 28M and 36M, remove differential assembly from carrier.
11. On Model 32M, straighten ear of lock and loosen nut. Loosen thrust block adjusting screw to move thrust block away from ring gear and permit removal of differential assembly. Remove oil collector drum attaching capscrews. Tilt differential to move ring gear away from pinion and lift differential assembly and oil collector drum from carrier.

RH — Right-hand LH — Left-hand Right and Left Hand is determined by standing at rear of vehicle and facing rear of axle (as installed in vehicle).

12. Unfasten and remove power divider from carrier. Discard divider case gasket. *On Models 22M, 28M and 32M, the differential must be removed from the carrier before removing the power divider. On Model 36M, the power divider may be removed with the differential assembled in the carrier.*

36M Power Divider

The 36M power divider is the same as Model 42M axle. Refer to 42M instructions given further on.

22M, 28M, 32M Power Divider

Note: Reference to "front" indicates the input companion flange side of power divider. "Rear" indicates differential carrier side.

1. Mount power divider in a repair stand that will permit rotation of the entire assembly for easier handling during reassembly.
2. Remove input flange nut and flange.
3. Loosen (but do not remove) input shaft front bearing cover, Fig. 31.
4. Remove nuts securing power divider case cover to case. Then, using a suitable puller, grip front bearing cover with puller legs and position puller screw against input shaft. Pull bearing cover and case cover assembly from case.
5. Remove loosened output flange nut, flat washer and flange.
6. Remove output shaft rear bearing cover. Remove oil seal and felt seal from bearing cover.
7. Working at rear end of output shaft, drive shaft out of rear bearing. Lift output shaft assembly from divider case, then remove rear bearing from divider case.
8. Remove inner bearing sleeve set screw and lockwasher from divider case.
9. Remove loosened drive pinion nut and tongued washer. Drive pinion assembly out rear of divider case. Remove outer bearing cone from bearing cage.
10. Remove pinion bearing cage and shims from divider case. *Note quantity and size of shims under cage flange for easier adjustment during reassembly.* If replacement is necessary, remove bearing cups from cage.
11. Remove cotter pin from input shaft inner nut. Temporarily place companion flange on input shaft. Hold flange and remove nut and "D" washer from input shaft.
12. Place divider case in press with front helical gear supported, then press on rear of input shaft until shaft end clears rear bearing. Remove input shaft assembly from divider case, and also rear bearing.
13. To disassemble input shaft, lift rear bearing spacer washer and rear helical side gear off input shaft. Place input shaft in press with splined end down and spacer washer resting on press plate. Then press input shaft out of component parts.
14. To disassemble inter-axle differential, punch mark differential cases for location on reassembly. Cut lockwire and remove nuts and bolts holding cases together. Separate cases, then remove spider, side pinions and thrust washers.
15. To disassemble drive pinion, remove sleeve from inner bearing. Place drive pinion in arbor press with teeth down and disassemble in two steps as follows: (a) Place press support plates under helical gear; then press pinion out of bearing spacer, inner bearing cone, long pinion spacer and helical gear. (b) Place bearing puller plates between pinion teeth and inner race of inner bearing and press pinion out of inner bearing. Remove pilot bearing from pinion, using press or suitable puller.
16. To disassemble output shaft, remove cotter pin from output shaft front nut. Temporarily install companion flange on rear end of output shaft. Hold flange and loosen output shaft front nut. Remove nut and "D" washer ("D" washer used on 32M only). Place output shaft in press with splined end down and helical gear resting on press plate. Press shaft through front bearing, spacer washer and helical gear. Remove helical gear spacer.

Power Divider Case Cover

Note: Either vacuum-operated, air-operated or mechanically-operated lockout may be used on "M" Series axles. The air-operated lockout is covered further on. The following instructions are for vacuum-operated type. Mechanically-operated lockout varies slightly from the vacuum type (refer to insert in Fig. 31 for components).

1. Remove loosened capscrews, lockwashers and front bearing cover from divider case cover. Remove oil seal and felt seal from bearing cover.
2. Remove sliding clutch and input shaft front bearing from case cover.
3. Push back shift lever boot. Remove clevis pin and shift lever. Unfasten and remove shift lever bracket from case cover.
4. Depress compression spring. Then remove pin, retainer washer and compression spring from push rod.
5. Withdraw shift fork and push rod from case cover. Remove seal retainer and felt seal from case cover.

Axle Differential, Models 22M, 28M

1. Punch mark differential cases for correct location in reassembly. Remove locknuts and bolts and lift off plain differential case.
2. Remove differential components from ring gear side of case.
3. Remove capscrew, lockwasher and lubricator from flanged differential case.
4. Remove bearing cones from differential cases, using split-type bearing puller.
5. To remove ring gear from flanged differential case, drill off the flat head of rivets (on ring gear side) and drive out rivets.

32M Axle Differential

1. Punch mark differential cases for correct location in reassembly. Cut lockwire and remove differential case cap screws. Lift off plain differential case.
2. Remove differential components ring gear side of differential case.
3. Remove bearing cones from differential case, using split-type bearing puller. To remove ring gear from flanged differential case, drill off flat head of rivets (on ring gear side) and remove rivets.

36M Axle Differential

1. Punch mark differential cases for correct location in reassembly. Cut lockwire and remove differential case capscrews. Lift off oil collector drum and plain differential case.
2. Remove differential components from flanged differential case.
3. Remove capscrew, lockwasher and differential lubricator from flanged differential case.
4. Remove bearing cones from differential cases, using split-type bearing puller. To remove ring gear from flanged differential case, drill off flat head of rivets (on ring gear side) and remove rivets.

REASSEMBLE

36M Power Divider

Note: The power divider assembly for Model 36M is the same as 42M. Refer to 42M instructions further on for procedures.

22M, 28M, 32M Power Divider

Note: Partially reassemble shafts and case covers before reassembling power divider case.

Power Divider Case Cover (Vacuum Type)

Note: The following instructions are for the vacuum-type lockout. Mechanically operated lockout varies slightly from the vacuum type (refer to insert in Fig. 31). The air-operated type is covered further on. A disassembled view of the vacuum-type lockout is shown in Fig. 32.

1. Install input shaft front bearing in divider case cover.
2. Place felt seal and seal retainer in recess in case cover. Insert push rod through case cover opening. Place compression spring and retainer washer on push rod, compress spring and install retainer washer pin. Coat spring and retainer washer with grease.
3. Install shift lever bracket and gasket over push rod and install capscrews and lockwashers.
4. Position shift lever on bracket, engaging end of lever with slot in push rod. Install clevis and cotter pins to connect lever to bracket.
5. Place boot on shift lever and bracket.
6. Depress shift lever and position sliding clutch in case cover, engaging shift fork in clutch grooves.

Output Shaft, Fig. 33

1. Press helical gear spacer on front

end of output shaft. Then press helical gear, spacer washer and front bearing on output shaft.

2. Temporarily place companion flange on rear end of output shaft. Place output shaft in vise with rear end down, gripping flange in vise jaws.
3. Install "D" washer (32M only) on output shaft. Install and tighten output shaft front nut to correct torque. Install cotter pin.

Drive Pinion, Fig. 34

1. Press pilot bearing on drive pinion and stake in four places (see Fig. 12).
2. Lubricate and press inner bearing on drive pinion, positioning bevel side of bearing toward pinion teeth.
3. On Models 22M and 28M, install oil seal in helical gear, positioning segment springs inside. Press helical gear on drive pinion, placing seal towards inner bearing. On Model 32M, press helical gear on pinion with short hub toward inner bearing.
4. Press long spacer on pinion. Press inner bearing cone on pinion.
5. If removed, press bearing cups in pinion bearing cage.
6. Lubricate pinion bearings. Temporarily place bearing cage, spacer, outer bearing cone, tongued washer and nut on pinion. Tighten nut to correct torque. Rotate pinion bearing cage while tightening nut. Check pinion bearing preload adjustment as already explained at the beginning of this chapter.
7. With pinion bearings correctly adjusted, remove temporarily installed nut, tongued washer, outer bearing cone and bearing cage from pinion.

Fig. 32 Disassembled view of vacuum-operated lockout

Fig. 33 Disassembled view of output shaft

Fig. 34 Disassembled view of drive pinion

Inter-Axle Differential, Fig. 35

1. Lubricate parts during reassembly. Place side pinions and thrust washers on spider journals. Assemble spider assembly and case halves, aligning punch marks made during disassembly. Install bolts and nuts to secure case halves. Tighten nuts to correct torque and lockwire.

Fig. 36 Disassembled view of input shaft

Input Shaft, Fig. 36

1. Temporarily install flange nut on front end of input shaft to protect threads during assembly. Place input in press, with shaft supported at nut and install parts on shaft as follows:
2. Place spacer washer on shaft.
3. Press front helical side gear bushing on shaft. Lubricate bushing, then install front helical side gear over bushing. *Bushing and gear must rest firmly against spacer washer.*
4. Place front spider splined washer on shaft. Place inter-axle differential on shaft, positioning bolt heads toward companion flange. Place rear spider splined washer on shaft, *making certain splines are engaged with input shaft splines.*
5. Press rear helical side gear bushing on shaft. Lubricate bushing, then install rear helical side gear over bushing. *Bushing and gear must rest firmly against splined washer.*
6. Place rear bearing spacer washer on shaft.
7. Temporarily place a "dummy sleeve" (1½" I.D. x 1" long), "D" washer and input shaft inner nut on shaft. Tighten nut to correct torque, then rotate shaft parts by hand. Gears and inter-axle differential should rotate freely without bind. After testing, remove temporarily installed parts.

Fig. 35 Disassembled view of inter-axle differential

Power Divider

1. Temporarily install companion flange on input shaft. Place input shaft in vise, with front end down and gripping flange in vise jaws.
2. Place power divider case, front side down, over input shaft. With rear bearing spacer washer on input shaft, install rear bearing in divider case bore and on input shaft. Install "D" washer and inner nut on shaft. Tighten nut to correct torque and install cotter pin.

Install output shaft rear bearing in

Fig. 37 Disassembled view of axle differential for Models 22M, 28M

Fig. 38 Disassembled view of axle differential for Models 32M, 36M

divider case. Lubricate bearing. With new felt seal and oil seal installed in rear bearing cover, install gasket and bearing cover on divider case. Install cover capscrews and lockwashers.

3. Remove divider case and input shaft assembly from vise.
4. Position divider case with front side up. Place output shaft in case, taking care not to damage rear bearing oil seal.
5. Place gasket and case cover on divider case. Make certain sliding clutch engages splines of input shaft. Fasten cover to case and tighten stud nuts to correct torque.
6. Install felt seal and oil seal in input shaft front bearing cover. Place gasket and bearing cover on case cover. Install capscrews and lockwashers but do not tighten until companion flange is installed.
7. Install companion flange, flat washer and nut. Tighten nut to correct torque and insert cotter pin. Now tighten front bearing cover capscrews to correct torque.
8. Install same quantity and size shims that were removed in disassembly on pinion bearing cage. Place shims and cage in divider case.
9. Insert drive pinion through opposite side of divider case until inner bearing cone is seated in inner bearing cup. Then place outer bearing cone, tongued washer and nut on drive pinion. Tighten nut to correct torque and insert cotter pin.
10. Install new cork seal in cage groove. Install cage cover and tighten nuts and capscrews to correct torque.
11. Insert bearing sleeve in divider case and over pinion inner bearing. Align sleeve hole with hole in case, then install set screw and lockwasher.
12. Loosen capscrews holding output shaft bearing cover. Install companion flange, flat washer and nut on output shaft. Tighten nut to correct torque and insert cotter pin. Tighten bearing cover capscrews to correct torque.

22M, 28M Axle Differential, Fig. 37

1. Rivet (cold) ring gear to flanged differential case, placing flat side head of rivets on ring gear side. Compress rivets to 34-38 tons on Model 22M or 40-42 tons on 28M.
2. Press bearing cones on differential cases. If removed, install oil lubricator in flanged differential case and secure with capscrew and lockwasher.
3. Lubricate parts during assembly. Place thrust washer and right-hand side gear in flanged differential case. Assemble side pinions and thrust washers to spider, then place this assembly on flanged differential case. Place left-hand side gear and thrust washer on side pinions.
4. Tap plain differential into place, aligning previously made punch marks. Draw case halves together with four bolts and lock nuts. Check assembly for free rotation. Install remaining bolts and locknuts and tighten all nuts to correct torque.

32M Axle Differential, Fig. 38

1. Rivet ring gear to flanged differential case, compressing rivets to 47-50 tons.
2. Press bearing cones on differential case. Lubricate parts during assembly.
3. Assemble differential parts in flanged differential case.
4. Tap plain differential case into place, aligning previously made punch marks. Do not install oil collector drum at this time, but assemble drum to case after differential is installed in carrier.
5. Install four large tapped head capscrews, equally spaced, to draw case halves together. Check assembly for free rotation. Install eight remaining capscrews and tighten all to correct torque. Lock with wire.

36M Axle Differential, Fig. 38

1. Rivet ring gear to flanged differential case, compressing to 39-41 tons.
2. Press bearing cones on differential cases. If removed, install oil lubricator in flanged differential case.
3. Assemble differential parts in flanged differential case. Then tap plain differential case half into place, aligning previously made punch marks.
4. Place oil collector drum on plain differential case. Install four capscrews to draw case halves together. Check assembly for free rotation. Install remaining capscrews and tighten all to correct torque.

Final Assembly

1. Using a new gasket, place power divider on differential carrier. Install and tighten stud nuts to correct torque.
2. On Models 22M, 28M and 36M, install differential in carrier as follows: Lubricate differential bearings. Place differential in carrier and install differential bearing cups, adjusters and caps, aligning punch marks previously made on caps. Install and finger-tighten bearing capscrews. Tighten adjusters to correctly seat bearings. Adjust ring gear and drive pinion as per instructions at the beginning of this chapter. When correctly adjusted, tighten bearing capscrews to correct torque. Install cotter pins to secure adjuster locks and lock capscrews with wire.
3. On Model 32M, install differential in in carrier as follows:
   (a) Lubricate differential bearings. Place oil collector drum on left-hand side of differential, but do not install capscrews. Place differential and drum in carrier and install bearing cups, adjusters and caps. Install and finger - tighten bearing cap screws.
   (b) Secure oil collector drum to plain differential with four capscrews and lockwashers.
   (c) Tighten bearing adjusters to seat bearings. Adjust ring gear and pinion as described at the beginning of this chapter.
   (d) With ring gear and pinion correctly adjusted, tighten bearing capscrews to correct torque. Install cotter pins to secure ad-

juster locks and lockwire capscrews.

(e) Tighten thrust block adjusting screw to position thrust block against ring gear. Loosen adjusting screw (⅛ to ¼ turn) to obtain .010-.015″ clearance between thrust block and ring gear. Tighten nut and bend ear of lock to secure adjustment.

Install Assembly In Axle Housing

1. Using a new gasket, install differential and power divider assembly in axle housing. Install capscrews or stud nuts and lockwashers. Tighten screws or nuts to correct torque.
2. Connect lockout shift lever.
3. Install axle shafts and connect propeller shafts.
4. Fill axle with correct lubricant.

MODEL 42M

Rearward Rear Axle

Instructions for the rearward rear axle are essentially the same as the forward rear axle except for removal of the power divider and drive pinion.

The rearward rear axle is not equipped with a power divider. The drive pinion for the rearward rear axle is mounted in a bearing cage at the front side of the differential carrier. The drive pinion can be removed and installed as a complete assembly, consisting of pinion, bearings, cage and companion flange.

Disassemble and reassembly of the differential assembly and countershaft are the same as instructions for the forward rear axle which follows:

DISASSEMBLE FORWARD REAR AXLE

1. Drain lubricant. Disconnect propeller shafts and remove axle shafts.
2. Disconnect lockout shift lever.
3. Unfasten and remove carrier and power divider from axle housing. *If preliminary inspection reveals that ring gear and drive pinion are satisfactory, check backlash with dial indicator and take a tooth contact pattern for reference and easier adjustment during reassembly.*
4. Remove pinion cage cover. Remove and discard cork seal. Hold input and output companion flanges and loosen (but do not remove) pinion nut.
5. Hold input flange and loosen (but do not remove) flange nut.
6. Hold output flange and loosen (but do not remove) flange nut.
7. Unfasten and lift power divider from differential carrier.

Differential Carrier, Fig. 39

1. Punch mark differential bearing caps and carrier for correct location during reassembly.
2. Remove bearing caps and lift differential out of carrier. Remove outer bearing races from differential cases.
3. Unscrew oil distributor plug, spring and distributor.
4. Punch mark countershaft bearing covers and carrier for correct location during reassembly. Remove covers from both sides.
5. Punch mark countershaft bearing cage (right-hand), bearing adjuster (left-hand) and differential carrier for correct location on reassembly. Then remove bearing cage and adjuster from carrier. Remove cage seal.
6. Remove oil reservoir from carrier.
7. Position herringbone pinion halfway through right-hand bearing cage opening, then tilt countershaft to position ring gear at top and lift out countershaft.

Differential

1. If match marks are not present, make marks to assure correct position of each case half in reassembly.
2. Unfasten and separate herringbone gear and case halves.
3. Lift herringbone gear and left-hand case off right-hand case and remove differential components.
4. Place side gear in vise and drive left-hand case from herringbone gear and case support.
5. Remove snap rings from case halves.
6. Remove bearing inner race from case halves using a split-type bearing puller.

Countershaft

1. Remove capscrews and oil collector disc.
2. If match marks are not present, make marks to assure correct position of ring gear on countershaft flange.
3. Remove ring gear from countershaft.
4. Remove bearing cones from countershaft using a split-type bearing puller.

Power Divider, Fig. 40

1. Remove input flange. Loosen (do not remove) capscrew on input shaft front bearing cover.
2. Remove divider cover to case stud nuts. Using suitable bearing puller, grip front bearing cover with puller legs and puller screw against input shaft. Pull bearing cover and case cover from case.
3. Remove output flange.
4. Working at rear end of output shaft, drive shaft end out of rear bearing. Lift output shaft from divider case, then remove bearing from case.
5. Remove inner bearing sleeve set screw from divider case.
6. Remove loosened pinion nut and tongued washer. Drive pinion out rear of divider case. Remove outer bearing cone from bearing cage.
7. Remove pinion bearing cage and shims from front side of divider case. *Note size and quantity of shims removed for easier adjustment in reassembly.* If replacement is necessary remove bearing cups from cage.
8. Remove input shaft assembly. This can easily be accomplished by temporarily installing companion flange and nut on end of shaft. Use flange to lift assembly from case.

Input Shaft & Inter-Axle Differential

1. Place input shaft in vise, gripping companion flange. Loosen and remove inner nut and tongued washer.
2. Place input shaft in press, with front helical side gear down and input shaft front spacer washer resting on press plates. Press shaft out of component parts.
3. Punch mark differential cases for correct location in reassembly. Cut lockwire and remove bolts holding cases together. Separate case halves and remove differential components.

Drive Pinion

1. On Model 36M, remove sleeve from inner bearing. Place pinion in press with pinion teeth down. Then first press pinion out of bearing spacer, inner bearing cone, long spacer and helical gear. Then press pinion out of inner bearing.
2. On Model 42M, remove pinion bearing spacer. Then first press pinion out of inner bearing cone, long spacer, helical gear and inner bearing sleeve. Then press pinion out of inner bearing spacer and inner bearing.

Output Shaft

1. Remove cotter pin from output shaft front nut. Temporarily place companion flange on shaft. Then remove front nut, tongued washer and flange.
2. Place output shaft in press with rear end of shaft down and helical gear resting on press plates. Press shaft out of front bearing, spacer washer and helical gear. Remove helical gear spacer.

Divider Case Cover (Air-Operated Lockout)

Either air-operated or mechanically-operated lockout may be used on 36M and 42M axles. Refer to insert in Fig. 31 for components of mechanically-operated lockout. The following instructions are for air-operated lockout.

1. Remove cover from shift cylinder body. Discard grommets. Remove nut, flat washer and grommet from push rod.
2. Remove shift cylinder body from case cover.
3. Remove compression spring from push rod. Remove sliding clutch and shift fork from case cover.
4. Remove front bearing cover and shims. Note size and quantity of shims removed for easier adjustment during reassembly. Remove oil seal and felt seal from bearing cover. Remove input shaft bearing from case cover.

REASSEMBLE

Divider Case Cover (Air-Operated), Fig. 41

1. Press front input shaft bearing in divider case cover.

Fig. 40 Disassembled view of power divider for Models 36M, 42M

2. Place felt seal and seal retainer in recess in case cover. Assemble push rod to shift fork and secure with nut, bolt and lockwasher.
3. Assemble shift fork and sliding clutch to case cover as follows: Partially insert push rod in case cover, engaging sliding clutch with shift fork, then push this assembly into correct mounting position in case cover.
4. Place compression spring, gasket and shift cylinder body over push rod and onto case cover. Secure body with capscrews and lockwashers. *Piston felt oilers should be soaked in SAE-30 oil for one hour prior to assembly.*
5. Install felt oilers on piston and insert piston assembly in body and on push rod. Place grommet on push rod, then install flat washer and nut.
6. Install grommets on cylinder cover, then install cover, nuts and lockwashers on shift cylinder body.

Output Shaft, Fig. 42

1. Press helical gear spacer on front end of shaft. Then press helical gear, bearing spacer washer and front bearing on shaft.
2. Temporarily place companion flange on rear end of shaft. Place shaft in

Reference to "FRONT" indicates the input companion flange side of power divider. "REAR" indicates the differential carrier side.

103. Pinion bearing cage cover
104. Lockwasher
105. Stud nut
106. Cap screw

vise with rear end down, gripping flange in vise jaws.

3. Install tongued washer on shaft. Install and tighten shaft front nut to correct torque. Install cotter pin.

Drive Pinion, Fig. 43

1. Lubricate and press inner bearing on pinion, positioning bevel side of bearing toward pinion teeth.
2. On Model 42M, press inner bearing spacer and inner bearing sleeve on pinion. *On Model 36M, install inner bearing sleeve when pinion is assembled to power divider case (spacer is not used).*
3. Press helical gear in pinion splines, making certain long hub is against inner bearing spacer (42M). On Model 36M, long hub is against inner bearing.
4. Press long pinion spacer and inner bearing cone on pinion.
5. If removed, press pinion bearing cups in bearing cage.
6. Lubricate pinion bearings. Temporarily place bearing cage, bearing spacer, outer bearing cone, tongued washer and nut on pinion. Tighten nut to correct torque, rotating bearing cage while tightening nut. Check pinion bearing preload as instructed at the beginning of this chapter.
7. With pinion bearing preload correctly adjusted, remove temporarily installed parts from pinion.

Inter-Axle Differential, Fig. 44

Lubricate parts during reassembly.

Fig. 41 Disassembled view of air-operated lockout mechanism

Fig. 42 Disassembled view of output shaft for Models 36M, 42M

Fig. 43 Disassembled view of drive pinion for Models 36M, 42M

Place side pinions and thrust washers on spider journals. Assemble spider assembly and case halves, aligning previously made punch marks. Secure case halves with bolts and nuts, tightening nuts to correct torque. Lock nuts with wire.

Input Shaft, Fig. 45

1. Temporarily install flange nut on front end of shaft to protect threads during assembly. Place shaft in a press, with shaft supported at nut and install parts on shaft as follows:
2. Place spacer washer on shaft. Press long helical side gear bushing on shaft. Lubricate bushing, then install front helical side gear on bushing. *Bushing and gear must rest firmly against spacer washer.*
3. Place front spider splined washer on shaft. Place inter-axle differential on shaft, positioning bolt heads toward companion flange. Place rear spider splined washer on shaft. *Make certain washer splines are engaged with shaft splines.*
4. Press short helical side gear bushing on shaft. Lubricate bushing, then install rear helical side gear over bushing. *Bushing and gear must rest firmly against splined washer.*
5. Place rear bearing spacer washer on shaft. Temporarily place a dummy sleeve (1½" I.D. x 1" long), tongued washer and shaft inner nut on shaft. Tighten nut to correct torque. Rotate shaft parts by hand; they should rotate freely without binding.
6. After testing assembly for free

Fig. 45 Disassembled view of input shaft for Models 36M, 42M

movement, remove temporarily installed parts. Then press rear bearing on shaft and install tongued washer and inner nut. Tighten nut to correct torque and install cotter pin.

Power Divider, Fig. 40

1. Position divider case with rear side up.
2. Lubricate and install output shaft rear bearing in divider case.
3. Install felt seal and oil seal in output shaft rear bearing cover. Using same size and quantity of shims removed at disassembly, install shims and bearing cover on divider case. Install (but do not tighten) cover capscrews and lockwashers until companion flange is installed.
4. *To check bearing clearance to determine thickness of shims required, install bearing cover on divider case without shims. Install and finger-tighten cover capscrews. Then, using a feeler gauge, measure clearance between bearing cover and divider case. This clearance measurement plus 003" would equal the thickness of shims required for correct bearing clearance.*
5. Rotate divider case to position front side up. Insert assembled input shaft, engaging rear bearing in bore of divider case.
6. Insert assembled output shaft in divider case, inserting end of shaft through rear bearing and taking care not to damage oil seal.
7. Using new case cover gasket, place divider case cover on divider case, engaging sliding clutch splines with input shaft splines. Install stud nuts and lockwashers. Tighten stud nuts to correct torque.
8. Install felt seal and oil seal in input shaft front bearing cover.

Fig. 44 Disassembled view of inter-axle differential for Models 36M, 42M

Fig. 46 Disassembled view of axle differential for Model 42M

Fig. 47 Disassembled view of countershaft for Model 42M

9. Using same size and quantity of shims removed in disassembly, install shims and bearing cover on divider case cover. Install capscrews and lockwashers but do not tighten until companion flange is installed. Check bearing clearance as explained for output shaft bearings above.
10. With front bearing cover capscrews loose, install companion flange on input shaft and secure with flange nut. Tighten nut to correct torque and install cotter pin. Tighten front bearing cover capscrews to correct torque.
11. Install same size and quantity of shims removed at disassembly on pinion bearing cage, then install cage on divider case. Temporarily install cage capscrews to retain cage during pinion installation.
12. With divider case rear side up, and with output shaft rear bearing cover capscrews loose, install companion flange on output shaft, taking care not to damage oil seal. Install and tighten flange nut to correct torque and install cotter pin. Tighten rear bearing cover capscrews to correct torque.
13. Lubricate pinion bearings. Install partially assembled pinion in divider case.
14. On Model 42M, position inner bearing sleeve in case bore and end of pinion through inner bearing cup. Align sleeve with set screw hole in case and install set screw and lockwasher.
15. Install pinion bearing spacer, outer pinion bearing cone, tongued washer and pinion nut. Tighten nut to correct torque and install cotter pin.
16. Remove temporarily installed bearing cage capscrews. Install new cork seal in cage groove. Install cover and tighten nuts and capscrews to correct torque.
17. On Model 36M, place inner bearing sleeve on pinion inner bearing and in divider case. Align sleeve with set screw hole in case and install set screw and lockwasher.

Differential, Fig. 46

1. Press bearing inner races on differential case halves and install snap rings.
2. Lubricate parts during reassembly.
3. Place herringbone gear on left-hand differential case. Place thrust washer and side gear in left-hand case. Assemble side pinions and thrust washers to spider, then place this assembly in left-hand case. Place right-hand side gear on side pinions.
4. Place side gear thrust washer on right-hand side gear. Position right-hand case over left-hand case, aligning matching marks on each case and, using bolts as guides, drive right-hand case into herringbone gear.
5. Install bolts with heads positioned on left-hand side and tighten to correct torque. *The four oversize bolts are mounted midway between spider arms.* Lock nuts with wire.

Countershaft, Fig. 47

1. Place ring gear on countershaft, aligning punch marks.
2. Place oil collector disc on opposite side of countershaft flange.
3. Install and tighten capscrews to correct torque. Lock screws with wire.
4. Press bearing cones on end of countershaft.

Final Assembly

1. Place countershaft in differential carrier.
2. Lubricate bearings. Install bearing cups.
3. Install left-hand bearing adjuster in carrier, engaging only two or three threads.
4. Install right-hand bearing cage.
5. Tighten bearing cage to preload countershaft bearings as explained at the beginning of this chapter.
6. With new gasket in place on carrier, install power divider on carrier. Install and tighten lockwashers and nuts to correct torque.
7. Adjust ring gear and pinion for proper tooth contact (explained earlier).
8. After correct adjustment, install countershaft bearing cover gaskets, bearing covers, capscrews and lockwashers. Tighten screws to correct torque.
9. Place oil reservoir in carrier.
10. Lubricate bearing outer races. If removed, place snap rings on differential bearings. Place outer races on inner races, then install in carrier. Install bearing caps, making certain that snap rings rest in grooves in carrier and caps.
11. Install bearing capscrews and lockwashers and tighten to correct torque. Lock screws with wire.
12. Insert oil distributor in carrier and install capscrew and lockwasher. Install spring, gasket and plug.
13. Install differential carrier and power divider in axle housing.
14. Connect lockout shift lever.
15. Install axle shafts and connect propeller shafts.
16. Fill axle with correct lubricant.

TIMKEN (Rockwell-Standard) DRIVING AXLES

LUBRICANT CAPACITIES

Lubricant capacities are given as a guide only. The capacities of two similar axles of the same series may vary considerably due to design changes and the vehicle manufacturers' installation. The actual service capacity may be determined by carefully measuring the amount of lubricant necessary to fill the assembly to the correct level and measuring the lubricant again when it is drained. The vehicle should be on a level floor when this inspection is made.

①—Add one pint of lubricant to pinion cage when new or reconditioned drive unit is installed.

②—Add two pints of lubricant to inter-axle differential housing when new or reconditioned drive unit is installed in addition to specified amount of lubricant in housing.

③—Housing cover 6½" deep overall.

Single Reduction Axles

DISASSEMBLE

Remove Carrier From Housing

1. Remove plug from bottom of housing and drain lubricant.
2. Remove axle shaft drive stud nuts and lockwashers.
3. Rap axle shafts sharply in center of flange to free dowels. Remove taper dowels and pull out axle shafts. *Prying shafts loose will damage hubs and oil seals.*
4. Disconnect universal at pinion shaft.
5. Remove carrier-to-housing stud nuts and washers. Loosen two top nuts and leave on studs to prevent carrier from falling.
6. Break carrier loose from axle housing with rawhide mallet.
7. Remove top nuts and washers and work carrier free, using puller screws in holes provided. A small pinch bar may be used to straighten carrier in housing bore. However, the end must be rounded to prevent indenting carrier flange. A roller jack may be used to facilitate removal of carrier.

Disassemble Carrier, Fig. 1

Double Reduction Thru-Drive Tandem Axles 226
Worm Drive Axles 233
Split Housing Axles 237
Electric Shift for Two Speed Axles 239

Fig. 1 Timken single reduction axle (typical)

1. To remove differential and gear assembly, cut lock wire. Remove capscrews and adjusting nut locks.
2. Center punch one differential carrier leg and bearing cap to identify for proper reassembly.
3. Remove bearing cap stud nuts or capscrews, bearing caps and adjusting nuts.
4. Loosen jam nut and back off thrust block adjusting screw.
5. Lift out differential and gear assembly.
6. Remove thrust block from inside of carrier housing.

Disassemble Differential & Gear

1. If original identification marks are not clear, mark differential case halves with a punch or chisel for correct alignment upon reassembly.
2. Cut lock wire, remove bolts and separate case halves.
3. Remove spider, pinions, side gears and thrust washers.
4. To remove ring gear rivets, carefully center punch rivets in center of head. Use a drill 1/32″ smaller than body of rivet to drill through head. Then press out rivets.
5. If necessary to remove differential bearings, remove with a suitable puller.

Removing Pinion & Cage

1. Hold flange or yoke with suitable tool and remove pinion shaft nut and washer.
2. Remove flange or yoke with a suitable puller. *Driving flange off will cause runout.*
3. Remove pinion cage stud nuts or capscrews.
4. Remove bearing cover and oil seal assembly.
5. Remove bearing cage, using puller screws in holes provided. *The use of a pinch bar will damage shims. Driving pinion from inner end with a drift will damage bearing lock ring groove.*
6. Wire shim pack together to facilitate adjustment on reassembly.

Disassemble Pinion & Cage

Both splined and tapered pinion shafts are used in single reduction carriers. Where the tapered shaft is used, the thrust bearings are adjusted by means of adjusting and lock nuts. On the splined shaft, this adjustment is secured with a selective spacer or spacer combination.

Splined Shaft

1. Tap shaft out of cage with a soft mallet and press shaft from cage.
2. Remove outer bearing from cage.
3. Remove spacer or spacer combination from pinion shaft.
4. If necessary to replace rear thrust bearing or radial bearing, remove with suitable puller.
5. Remove oil seal from bearing cover.

Tapered Shaft

1. Straighten lock washer and remove lock nut, washer, adjusting nut and thrust washer.
2. Tap pinion out of cage with a soft mallet or press shaft from cage.
3. Remove bearing from cage.
4. Remove bearings from shaft with suitable puller if necessary.
5. Remove oil seal from bearing cover.

REPAIRS

1. Replace all worn or damaged parts. Hex nuts with rounded corners, all

lock washers, oil seals and gaskets should be replaced.

2. Remove nicks, mars or burrs from machined or ground surfaces. Threads must be clean and free to obtain accurate adjustment and correct torque. A fine mill file or India stone is suitable for this purpose. Studs must be tight prior to reassembling of parts.
3. All bronze bushed differential pinions should be ball burnished after bushing installation. Install bushing with a small stepped drift. The small O.D. should be .010″ smaller than the bushing burnished I.D. and 1½ times bushing length. Always install bushings so end is even with I.D. chamfer or about $\frac{1}{16}$″ below the spherical surface.
4. When assembling components, use a press where possible.
5. Tighten all nuts to the specified torque (see torque limits following service instructions). Use soft iron locking wire to prevent possibility of wire breakage.
6. The burrs, caused by lockwashers, at the spot face of stud holes of cages and covers should be removed to assure easy reassembly of these parts.

REASSEMBLY OF CARRIER

Pinion & Cage

Splined Shaft

1. Press rear thrust and radial bearings firmly against pinion shoulders with a suitable sleeve that will bear only on bearing inner race.
2. Install radial bearing lock ring and squeeze ring into pinion shaft groove with pliers.
3. If new cups are to be installed, press firmly against pinion bearing cage shoulders.
4. Lubricate bearings and cups with light machine oil.
5. Insert pinion and bearing assembly in pinion cage and position spacer or spacer combination over pinion shaft.
6. Press front bearing firmly against spacer.
7. Rotate cage several revolutions to assure normal bearing contact.
8. While in press under pressure, check bearing preload torque. Wrap soft wire around cage and pull on a horizontal line with a spring scale, Fig. 2. If a press is not available, the pinion nut may be tightened to the correct torque and preload checked.
9. The correct pressures and torque for checking pinion bearing preload are as follows:

Thread Size	*Pressure*	*Torque, Lb. Ft.*
1″ x 20	6 tons	300-400
1¼″ x 18	11 tons	800-1100
1½″ x 12	14 tons	800-1100
1½″ x 18	14 tons	800-1100
1¾″ x 12	14 tons	800-1100

10. Use starting torque, not rotating torque. If rotating torque is not within 5 to 15 pound inches, use thinner spacer to increase or thicker spacer to decrease preload. Assuming pinion cage diameter to be 6″, the radius would be 3″ and with 5 pounds pull would equal 15 pound inches of preload torque.

Fig. 2 Measuring pinion bearing preload

11. Press flange or yoke against forward bearing and install washer and pinion shaft nut.
12. Place pinion and cage over carrier studs, hold flange and tighten pinion shaft nut to correct torque. Flange must be held with a suitable tool or fixture to tighten nut.
13. Recheck pinion bearing preload torque. If rotating torque is not within 5 to 15 pound inches, repeat the foregoing procedure.
14. Hold flange and remove pinion shaft nut and flange.
15. Lubricate pinion shaft oil seal and cover outer edge of seal body with a non-hardening sealing compound. Press seal against cover shoulder with a seal driver.
16. Install new gasket and bearing cover.
17. Press flange against forward bearing and install washer and pinion shaft nut.
18. Tighten to correct torque and install cotter key. *Do not back off nut to align cotter key holes.*

Tapered Shaft

1. Press rear thrust and radial bearings firmly against pinion shaft shoulder.
2. Install radial bearing lock ring and squeeze ring into pinion shaft groove with pliers.
3. If new cups are to be installed, press firmly against pinion cage shoulders.
4. Lubricate bearings and cups with light machine oil.
5. Install forward bearing, thrust washer and adjusting nut.
6. Install new lockwasher and lock nut.
7. Adjust pinion bearing preload to 5 to 15 pound inches with lock nut tightened securely against washer. *Lock nut must be tight to secure correct preload.*
8. Bend lock washer when correct preload has been obtained.
9. Lubricate pinion shaft oil seal and cover outer edge of seal body with a non-hardening sealing compound. Press seal against cover shoulder with a seal driver.
10. Install new gasket and bearing cover. Cover should be carefully installed to prevent cutting seal on keyway.
11. Install key, press flange on taper and install washer and pinion shaft nut.
12. Tighten to correct torque and install cotter key. *Do not back off nut to align cotter key holes.*

Install Pinion & Cage

1. Install correct shim pack. Locate thin shims on both sides for maximum sealing ability.
2. Position pinion and cage assembly over studs and tap into position with soft mallet.
3. Install lock washers and stud nuts or capscrews. Tighten to correct torque.

Assemble Differential & Gear

1. Rivet ring gear to case half with new rivets. Rivets should not be heated, but always upset cold. When the correct rivet is used, the head being formed will be at least ⅛″ larger in diameter than the rivet hole. The head will then be approximately the same height as the preformed head. Excessive pressure will cause distortion of the case holes and result in gear eccentricity. Bolts are available for service replacement of rivets.
2. Lubricate differential case inner walls and all component parts with axle lubricant.
3. Position thrust washer and side gear in ring gear and case half, Fig. 3.
4. Place spider with pinions and thrust washers in position.
5. Install component side gear and thrust washer.
6. Align mating marks and position component case half. Draw assembly together with four bolts or capscrews equally spaced.
7. Check assembly for free rotation of differential gears and correct if necessary.
8. Install remaining bolts and capscrews. Tighten to correct torque and lock with wire.
9. If bearings are to be replaced, press squarely and firmly on differential case halves.

Install Bearing Cups In Carrier Leg Bores

1. Temporarily install bearing cups or threaded adjusting rings and bearing caps. Tighten capscrews to proper torque.

Fig. 3 Differential pinion and side gear assembly

Fig. 4 Adjusting differential bearing preload

Fig. 5 Painting ring gear teeth for obtaining tooth contact impressions

2. The bearing cups must be a hand push fit in the bores, otherwise the bores must be re-worked with a scraper or some emery cloth until a hand push fit is obtained. Use a blued bearing cup as a gauge and check the fits as work progresses.

Install Differential & Gear

1. After checking related parts, coat differential bearing cones and cups with rear axle lubricant.
2. Place cups over assembled bearing cones and position differential assembly in carrier.
3. Insert bearing adjusting nuts and turn hand-tight against bearing cups.
4. Install bearing caps in correct location as marked and tap lightly in position. *If bearing caps do not position properly, adjusting nuts may be cross-threaded. Remove caps and reposition the adjusting nuts. Forcing caps into position will result in irreparable damage to carrier housing or bearing caps.*
5. Install flat washers where used and stud nuts or capscrews. Tighten to correct torque.

Adjusting Differential Bearing Preload

1. Using dial indicator at back face of ring gear, Fig. 4, loosen bearing adjusting nut *on side opposite gear only* enough to notice end play on dial indicator.
2. Tighten same adjusting nut only enough to obtain zero end play.

Fig. 6 Location, size and shape of tooth contacts

3. Check gear for runout. If runout exceeds .008″, remove differential and check for cause.
4. Tighten adjusting nuts *one notch each* from zero end play to preload differential bearings.

Check Ring Gear Backlash

If original gears are reused the backlash should be the same as before disassembly. For new gears the new backlash should be from .006″ to .012″. Adjust backlash by moving ring gear only. This is done by backing off one adjusting ring and advancing the opposite ring the same amount.

Check Gear Tooth Contact

Temporarily bolt up the pinion and cage to the differential carrier and coat the ring gear teeth with oiled red lead, Fig. 5. When the pinion is rotated, the red lead is squeezed away by the contact of the teeth, leaving bare areas the exact size, shape and location of the contacts. If these contacts are not acceptable, shims must be added to or removed from the shim pack located between the pinion cage flange and differential carrier housing. It may be necessary to make several attempts at the right selection of shims to obtain the correct tooth contact, Fig. 6.

Fig. 7 Showing thrust block placed on back face of ring gear

Fig. 8 Adjusting clearance between thrust block and back face of ring gear

Sharper tooth contact impressions may be obtained by applying a small amount of resistance to the gear with a flat steel bar and using a wrench to rotate the pinion. When making adjustments, check the drive side of the ring gear teeth. Coast side contact should be automatically correct when drive side contact is correct. As a rule coating about 12 teeth is sufficient for checking purposes.

Install Thrust Block

1. Remove thrust block adjusting screw and lock nut.
2. Place thrust block on rear face of ring gear, Fig. 7, and rotate gear until hole in thrust block is aligned with adjusting screw hole.
3. Install adjusting screw and lock nut and tighten screw enough to locate thrust block firmly against back face of ring gear.

CAP SCREWS AND STUD NUTS

Fig. 9 Torque settings for Timken single reduction axles. Specifications apply to parts coated with machine oil. For dry (or "as received") parts, increase torque 10%. For parts coated with multi-purpose gear oil, decrease torque 10%. Nuts and studs to use same torque as for driving the stud

4. To secure correct adjustment of .010" to .015" clearance Fig. 8, loosen adjusting nut 1/4 turn and lock securely with nut.
5. Recheck to assure minimum clearance of .010" during full rotation of ring gear.

Install Carrier In Housing

1. Install new gasket over housing studs.
2. Roll carrier into position on roller jack. Start carrier into housing with four flat washers and nuts equally spaced. *Do not drive carrier into housing with a hammer at the carrier stud flange. The flange may easily be distorted and cause severe oil leakage.*
3. Install lock washers and stud nuts on any studs under carrier housing offsets. *It is impossible to start these nuts after carrier is drawn into housing.*
4. Tighten the four nuts over flat washers alternately to draw carrier squarely into axle housing.
5. Remove nuts and flat washers. Install taper dowels, lock washers and stud nuts. Tighten to correct torque.
6. Connect universal at pinion shaft and install axle shafts.

Lubrication

1. Fill axle housing to correct level with specified lubricant.
2. Lubricate universal joint.
3. Jack up both rear wheels and operate vehicle in high transmission gear at approximately 25 mph for five minutes to assure satisfactory lubrication of all parts. *Do not operate with one wheel jacked up. Operation in this manner will result in overheating the differential spider with resultant galling or shearing of spider pins.*

Double Reduction Axle

DISASSEMBLE

The procedures for removing the differential carrier from the axle housing and removing the differential and drive gear from the carrier is the same as outlined for the single reduction axle. During the procedure which follows, refer to Figs. 1 and 2.

Differential Case & Drive Gear

1. If original identification marks are not clear, center punch case halves for correct alignment on reassembly.
2. Cut lock wire, remove long bolts and separate case halves.
3. Remove spider, pinions, side gears and thrust washers.
4. Remove short bolts and separate gear from case half.
5. Remove differential bearings with suitable puller if necessary.
6. Remove drive gear rivets as directed for the Single Reduction Axle.

Pinion & Cage Assembly

1. Remove cage stud nuts or capscrews and lockwashers. Lift out cage assembly. *If cage is not free, tap it loose, using a soft drift on inner face of pinion or use puller screws in holes provided.*
2. Wire shim pack together to facilitate adjustment on reassembly.
3. Place pinion cage over carrier studs or secure with three capscrews. Hold flange and remove pinion shaft nut.
4. Press pinion shaft out of flange or yoke and cage.
5. Remove adjusting spacers or shims.
6. If necessary to renew the pinion or rear bearing, remove bearing with suitable puller.
7. Press front bearing and pinion shaft oil seal from cage. On assemblies where bearing cover is used, remove seal assembly from cover.

Cross Shaft Assembly

1. Remove stud nuts or capscrews and lockwashers from cross shaft bearing cage (side opposite drive gear).
2. Force off bearing cage with small pinch bar between back of gear and carrier housing (puller screw holes are also provided).

3. Wire shim pack together to facilitate adjustment on reassembly.
4. Remove cross shaft assembly.
5. Cut lock wire, remove capscrews and bearing retainer plate from gear end of shaft.
6. Press shaft from gear and bearing.
7. If necessary to replace bearing, remove bearing from opposite end of cross shaft with a suitable puller.
8. If necessary to replace bearing cups, remove cross shaft bearing cover or cage (drive gear side). Wire shim pack together to facilitate adjustment on reassembly.

REPAIRS

Precautions when making repairs on this axle are the same as outlined for the Single Reduction axle.

REASSEMBLY

Cross Shaft

1. Insert key and start shaft into drive gear in line with keyway or splines.
2. Press shaft squarely into drive gear. Gear must be firmly against cross shaft shoulder. *To facilitate installation, drive gear may be heated in oil from 200 to 250 degrees F.* Install capscrews where used.
3. Press bearing firmly against cross shaft shoulder on spur gear end.
4. Install bearing retainer plate and capscrews on drive gear end. Tighten to correct torque and lock with soft wire.
5. Lubricate cross shaft bearings and cups with light machine oil.
6. If bearing cover or cage on drive gear side has been removed, replace using the correct shim pack. Tighten stud nuts or capscrews to correct torque. If cover has not been removed, retighten stud nuts or capscrews to correct torque.
7. Ease cross shaft assembly past differential bearing supports and position in bearing cup.
8. Press bearing firmly against drive gear, using a suitable sleeve.
9. Install correct shim pack and start cross shaft bearing cage into carrier housing.
10. Tap bearing cage into position with soft mallet. Install lockwashers and stud nuts or capscrews and tighten to correct torque.
11. Rotate assembly several revolutions before checking bearing preload to assure full bearing contact.
12. Check cross shaft bearing preload torque. Wrap soft wire around pinion and pull on a horizontal line with a spring scale, Fig. 3. Assuming spur gear diameter to be 4″, the radius would equal 2″. Thus, five pounds pull on the scale would equal 10 pound-inches bearing preload torque. Use rotating, not starting torque.
13. To obtain correct preload torque of 5 to 15 pound-inches, add or remove shims from pack under bearing cage on side opposite bevel gear.

Assemble Pinion & Cage

1. Press rear bearing squarely and firmly against pinion gear shoulder.
2. Press bearing cups squarely and firmly pinion cage shoulder.
3. Lubricate bearing and cups with light machine oil.
4. Insert pinion and bearing assembly in pinion cage.
5. Install selective spacer over pinion shaft with bevel side toward pinion shaft shoulder.

Fig. 1 Cutaway view of Timken Double Reduction Axle

Fig. 3 Checking preload torque on cross shaft bearing

Fig. 4 Checking preload torque on pinion bearing

6. Press front bearing squarely and firmly against selective spacer with a suitable sleeve.
7. Rotate cage several revolutions to assure normal bearing contact.
8. While in press under pressure, check pinion bearing preload torque. Wrap soft wire around pinion cage and pull on a horizontal line with a spring scale, Fig. 4. If a press is not available, the preload may be checked with the flange or yoke installed and the nut tightened to the correct torque. The correct pressures or torques for checking pinion bearing preload are as follows:

Thread Size	*Pressure*	*Torque, Lb. Ft.*
1″ x 20	6 tons	300-400
1¼″ x 18	11 tons	700-900
1½″ x 12	14 tons	800-1100
1½″ x 18	14 tons	800-1100
1¾″ x 12	14 tons	800-1100

9. Assuming pinion cage diameter to be 6″ the radius would be 3″. Four pounds pull on the scale would equal 12 pound-inches bearing preload torque. Use rotating, not starting torque. If rotating torque is not within 5 to 15 pound-inches, use a thinner spacer to increase or a thicker spacer to decrease bearing preload.
10. Press flange or yoke firmly against pinion forward bearing.
11. Place pinion and cage assembly over carrier studs or secure with capscrews. Hold flange and tighten pinion shaft nut to correct torque. If rotating torque is not within 5 to 15 pound-inches, repeat foregoing procedure.
12. Hold flange and remove pinion shaft nut and yoke or flange.
13. Lubricate pinion shaft oil seal. Coat outer edge of seal body with a non-hardening sealing compound and press seal firmly against cage or cover shoulder. Install bearing cover where used with capscrews.
14. Reinstate flange or yoke. Tighten pinion shaft nut to correct torque.

Install Pinion & Cage

1. The oil passage holes in carrier housing, gasket, shim pack and pinion bearing cage must be aligned.
2. Install cross shaft assembly as outlined previously.
3. Install correct shim pack.
4. Install pinion cage assembly, lockwashers and stud nuts or capscrews. Tighten to correct torque.

Checking Drive Gear Lash

Generally, if original gears are being installed, red leading of teeth will not indicate the same contact as new gears and can be misleading. Gears that have been in service for long periods form running contacts due to wear of teeth. Therefore, th thickness of the original shim pack plus approximately .015″ additional shim stock should be maintained to check gear lash. In the event that gear lash is in excess of maximum tolerance, as stated under gear adjustment, reduce gear lash only in the amount that will avoid overlap of the worn tooth

Fig. 11 Torque specifications for capscrews or stud nuts on Timken Double Reduction Axles. Torques given apply to parts coated with machine oil. For dry (or "as received") parts, increase torques 10%. For parts coated with multi-purpose gear oil, decrease torques 10%. Nuts on studs to use same torque as for driving the stud

section, Fig. 5. Bevel gear lash can only be reduced to a point of maintaining smooth rotation of bevel gears.

Smoothness or roughness can be noted by rotating the bevel gear. If a slight overlap, Fig. 5, takes place at the worn tooth section, rotation will be rough. Generally with the original gears, tone should be satisfactory. Fig. 6 shows how a dial indicator is used to chek bevel gear lash.

Drive Gear Adjustment for Correct Tooth Contact

Checking tooth contact is accomplished by means of oiled red lead applied lightly to the drive gear teeth. When the pinion is rotated, the red lead is squeezed away by the contact of the teeth, leaving bare areas the exact size, shape and location of the contacts.

With adjustments properly made (pinion at correct depth and backlash set at .010") the contacts shown in Figs. 7 and 8 will be procured. The area of contact favors the toe and is centered between the top and bottom of the tooth.

The hand-rolled pattern shown in Fig. 7, will result in a pattern centered in the length of the tooth when the gears are under load, shown in Fig. 8. The loaded pattern will be almost full length and the top of the pattern will approach the top of the gear tooth.

After the correct contacts shown have been established with a backlash of .010", open the backlash to measure .020 to .026."

Recheck Cross Shaft Bearing Preload

1. Remove pinion and cage, keeping shim pack intact.
2. Tighten cross shaft bearing cage and cover stud nuts or capscrews to the correct torque.
3. Recheck cross shaft bearing preload torque.
4. Add or remove shims from pack under cross shaft bearing cage on the side opposite drive gear only as necessary to obtain correct bearing preload torque.
5. Replace pinion cage and install lockwashers, nuts or capscrews.
6. Tighten bearing cage stud nuts to correct torque.
7. Reinstall pinion and cage over shim pack determined by correct gear adjustment.
8. Install lockwashers and stud nuts and tighten to correct torque.

Drive Gear Backlash Adjustment

1. Adjust gear backlash to .020 to .026" (regardless of what markings might be etched on the gear set) by transposing cross shaft bearing cage or cover shims.
2. To move gear away from pinion, remove shims from pack under cross shaft bearing cage on opposite side of gear and add shims of equal thickness to pack under cross shaft bearing cover or cage on gear side. Shims should be transposed in this manner to maintain established preload.
3. To move gear toward pinion, remove shims from pack from under cross shaft bearing cover or cage on the gear side and add shims of equal thickness to pack under cross shaft bearing cage on the opposite side.

Assemble Differential & Spur Gear

When new spur gears or a new differential case is installed, the differential case holes must be line-reamed with the gear in order to assemble, using correct size bolts or rivets.

Type Using Long and Short Bolts, Fig. 9

1. Join spur gear to either differential case half with short bolts.
2. Lubricate differential case inner walls and all component parts with axle lubricant.
3. Install thrust washer and side gear in one of the case halves. Place spider with pinions and thrust washers in position. Install other side gear and thrust washer.
4. Check assembly for free rotation and correct if necessary.
5. Install remaining bolts and tighten to correct torque.
6. Install lock wire.
7. Press differential bearings squarely and firmly on differential case halves.

Type Using Rivets or Short Bolts

1. Lubricate differential case inner walls and all component parts with axle lubricant.
2. Install thrust washer and side gear in one of the differential case halves.
3. Position spur gear on case half.
4. Place spider with pinions and thrust washers in position and install other side gear and thrust washer.
5. Align mating marks and position other case half.
6. Draw either bolted or riveted assembly together with four bolts equally spaced and check for free rotation of differential gears.
7. Install remaining bolts or rivets together as required. Install rivets as directed for the Single Reduction Axle.

Final Assembly & Installation

The installation of bearing cups in carrier leg bores, of differential assembly in carrier and of carrier in axle housing is the same as outlined for the Single Reduction Axle.

Two Speed Double Reduction Axles

Fig. 1 shows the various types of Timken two speed double reduction drive axles. The first reduction is through a hypoid pinion and gear. The hypoid pinion and gear set operates in conjunction with either of two sets of helical gears and pinions of different ratios. This second reduction is selective between high and low ratio.

The hypoid pinion is mounted on two tapered roller bearings in a pinion cage. The hypoid gear is locked on the cross shaft by a press fit and key. The cross shaft is mounted on tapered roller bearings and carries two free-rolling helical pinions. Both helical pinions engage helical gears attached to the differential, which is mounted on tapered roller bearings.

To establish and maintain differential bearing preload, these axles may incorporate any one of the three types of carrier leg and cap machining shown in Figs. 2, 3 and 4.

REMOVING CARRIER FROM AXLE HOUSING

Front Mounted Type

1. Drain lubricant from housing.
2. Remove axle shafts.
3. Disconnect U-joint at pinion shaft.
4. Disconnect power shift unit.
5. Remove carrier-to-housing stud nuts, leaving two top nuts partially screwed on studs to prevent carrier from falling.
6. Break carrier loose from axle housing with a soft mallet. Remove tapered dowels if present.
7. Place a roller jack under carrier, remove two top nuts and work carrier free, using puller screws in holes provided. A small pinch bar may be used to straighten carrier in housing bore. However, be sure the end is rounded to prevent indenting carrier flange circle.

Top Mounted Type

1. Perform Steps 1 through 5 as outlined above.
2. Then break carrier loose from housing with soft mallet and remove tapered dowels. If necessary, back out studs.
3. Pull carrier straight out of housing with chain falls, boom, "A" frame or puller screws. A small pinch bar may be used to straighten carrier in housing bore. However, be sure end of punch is rounded to prevent indenting carrier flange circle.

DISASSEMBLE, FIG. 5

1. Center punch one carrier leg and bearing cap to identify for proper reassembly.
2. Remove capscrews and adjusting ring locks (where used).
3. Remove bearing cap, screws, bearing cups and adjusters.

FRONT MOUNTED DRIVE UNIT

TOP MOUNTED DRIVE UNIT

FRONT MOUNTED GEAR TRAIN

TOP MOUNTED GEAR TRAIN

Fig. 1 Timken two-speed double reduction axles

not clear, center punch differential case halves for correct alignment upon reassembly.

6. Separate case halves and remove differential components.
7. Remove short bolts or rivets and separate gears from case when gear or case is to be replaced. Remove differential bearings with suitable puller when desired.
8. Hold flange and remove pinion shaft nut. Remove attaching capscrews and lift out pinion cage. If cage is not free, tap loose with a soft drift on inner face of pinion or use puller screws in holes provided.
9. Wire pinion cage shims together to facilitate adjustment on reassembly.
10. Press pinion shaft out of flange and cage. Remove adjusting spacers.
11. If necessary to replace pinion or rear bearing, remove bearing with suitable puller.
12. Press front bearing and pinion shaft oil seal from cage.

Remove Side Mounted Shift Unit

1. Remove lockwire at fork locking screw.
2. Loosen lock nut on shift fork lock screw and remove screw and nut.
3. Remove two shift unit stud nuts and washers.
4. Remove shift unit and shaft assembly and lift out shift fork.
5. Tap sleeve from carrier with a soft mallet.
6. Wire shim pack to keep intact for proper adjustment on reassembly.

Remove Front Mounted Shift Unit

1. Remove four shift unit adapter screws and washers.
2. Remove shift unit and adapter assembly from carrier.

Remove Cross Shaft

1. Remove capscrews from cross shaft bearing cage (side opposite hypoid gear).
2. Force out bearing cage with small pinch bar between back of hypoid gear and carrier housing (puller screw holes also provided).
3. Wire shim pack together to facilitate adjustment on reassembly.
4. On models with front mounted shift units, remove lockwire and set screw holding shift fork on shift shaft. Slide shaft out and remove fork from inside housing.
5. Thread out cross shaft assembly. Some wide ratio carriers will require removal of high speed pinion and bearing from cross shaft before removing cross shaft from carrier. On these units, proceed as follows:
6. Raise cross shaft through cage bore. Remove bearing retaining plate. Use puller to remove bearing. Remove high speed helical pinion from cross shaft. Thread out cross shaft. *Some wide range carriers will permit using cross shaft to that high speed pinion and bearing can be pulled off together.*

Disassemble Cross Shaft

1. Remove capscrews and retaining plates.
2. Press cross shaft from hypoid gear and bearing. Lift off helical pinion and remove shift collar, poppets and springs.
3. Replace shift collar and press shaft through remaining helical pinion and bearing.
4. If necessary to replace cross shaft bearing cups, remove cross shaft bearing cover (hypoid gear side).

Fig. 2 Type with threaded adjusting rings on both sides. This type positions differential as well as preloading bearings by moving threaded rings in or out

Fig. 3 Type with threaded ring on one side and split ring on opposite side. Split ring and groove locates differential whereas threaded ring is moved in or out to preload bearings

Fig. 4 Type with split rings on both sides. Bearing preload is established by using various thickness split rings. Differential positioning is automatic

Wire shim pack together to facilitate adjustment on reassembly.

5. Remove cups from cages with suitable puller. Cup in cover side of carrier can be removed by tapping.

Service Notes

1. Replace all worn or damaged parts. Hex nuts with rounded corners, all lock washers, oil seals and gaskets should be replaced.
2. Remove nicks, mars or burrs from machined or ground surfaces. Threads must be clean and free to obtain accurate adjustment and correct torque. A fine mill file or India stone is suitable for this purpose. Studs must be tight prior to reassembling parts.
3. All bronze bushed differential pinions should be ball burnished after bushing installation. Install bushing with small stepped drift. The small O.D. should be .010″ smaller than the bushing burnished I.D. and 1½ times bushing length. Always install bushings so end is even with the I.D. chamfer or about $\frac{1}{16}$″ below the spherical surface.
4. Burrs, caused by lock washers at the spot face of stud holes of cages and covers should be removed to assure easy reassembly of these parts.

Fig. 5 Exploded view of Timken two speed double reduction axle of the front mounted type with vacuum shift unit

Fig. 6 Hypoid pinion and cage assembly

Fig. 7 Checking pinion bearing preload

REASSEMBLE CARRIER

Hypoid Pinion & Cage

1. Refer to Fig. 6. Press rear bearing squarely and firmly against pinion shaft shoulder.
2. Press bearing cups squarely and firmly against pinion cage shoulder.
3. Lubricate bearing and cups with light machine oil.
4. Insert pinion and bearing in cage.
5. Install selective single or combination spacers over pinion shaft.
6. Install single spacer with O.D. bevel toward outer bearing cone. Install two combination spacers with I.D. bevels opposite each other and large flat faces together. *Spacers must be installed in this manner to prevent interference with outer bearing cone roller cage.*
7. Press front bearing squarely and firmly against selective spacer with suitable sleeve.
8. Rotate cage several revolutions to assure normal bearing contact.
9. While in press under pressure, check pinion bearing preload torque. Wrap strong cord around pinion cage and pull on a horizontal line with a spring scale, Fig. 7.
10. If a press is not available, pinion nut may be tightened to the correct torque and preload checked as follows:

Fig. 8 Wide range ratio and some conventional ratio cross shaft assembly

Fig. 9 Most conventional ratio cross shaft assemblies

Pinion Shaft Thread Size	Nut Torque Lbs. Ft.	Equivalent Pressure In Tons
1″ x 20	300-400	6
1¼″ x 18	700-900	11
1½″ x 12	800-1100	14
1½″ x 18	800-1100	14
1¾″ x 12	800-1100	14
2″ x 16	800-1100	14
2⅛″ x 12	800-1100	14

Example: Assuming pinion cage diameter to be 6″, the radius would be 3″, and with 4 pounds pull on scale would equal 12 inch pounds bearing preload torque.

11. Read rotating pounds pull on scale (not starting pounds pull). If rotating torque is not within 5 to 15 inch pounds, use a thinner spacer to increase or a thicker spacer to decrease preload torque.
12. Press flange or yoke firmly against forward pinion bearing.
13. Use carrier as a convenient holding fixture for pinion and cage assembly. Hold flange and tighten shaft nut to correct torque.

Fig. 10 Checking helical pinion end play with feeler gauge

14. Recheck pinion bearing preload torque. If rotating torque is not within 5 to 15 inch pounds repeat foregoing procedure.
15. Hold flange and remove pinion shaft nut and yoke or flange.
16. Lubricate pinion shaft oil seal. With suitable sleeve, press seal firmly against bearing cage shoulder.
17. Reinstall yoke or flange and tighten nut to correct torque.
18. Remove pinion and cage assembly from carrier.

Cross Shaft Assembly

1. Refer to Figs. 8 and 9. Lubricate inner bearing surfaces on helical pinions with axle lubricant.
2. Position high or low speed helical pinion (depending on type of carrier) on cross shaft with splined row of teeth toward cross shaft teeth.
3. Install key and start cross shaft and pinion in hypoid gear in line with keyway.
4. Press shaft squarely into hypoid gear. *Cross shaft of all wide range ratio carriers and a number of conventional ratio carriers employ no hypoid gear shoulder. Extreme care must be exercised to assure pinion end play of .010″ minimum.*
5. Check helical pinion end play with feeler gauge, Fig. 10. End play must be .010″ minimum to .026″ maximum. *On conventional ratio carriers where definite gear stop is provided by cross shaft shoulder, it is still necessary to have this end play. To facilitate installation, hypoid gear may be heated in oil to 200-250°.*
6. Press bearing firmly against hypoid gear using suitable sleeve. Install bearing retaining plate and capscrews.
7. Install poppets and springs and coat with axle lubricant.
8. Align all three tapered shift collar splines with poppets and position with shift collar marked "low side" toward low speed helical pinion. Due to tooth spacing, some shift collars can be assembled in one position only. *Some wide range ratio carriers will require installing cross shaft in carrier before assembly of high speed helical pinion and bearing on cross shaft. On these units skip Steps 9 to 12.*
9. Install opposite helical pinion (high or low speed depending on carrier) with splined teeth toward cross shaft teeth.
10. Press cross shaft bearing squarely and firmly against cross shaft shoulder using suitable sleeve.
11. Check low speed pinion end play which must be a minimum of .010″. *Less than .010″ may result in seizure.*
12. Install bearing retaining plates and capscrews.

Install Cross Shaft In Carrier

Gaskets at the pinion cage, cross shaft covers and cages have not been used in units produced for several years. Therefore, when assembling a drive unit formerly using gaskets, add approximately .015″ shim stock to original shim pack to maintain correct bearing preload and gear adjustment. Thin shims should be located on both sides of pack to obtain maximum sealing ability.

On wide range ratio carriers requiring

Fig. 11 Checking cross shaft bearing preload

assembly of high speed helical pinion and bearings after cross shaft is in the carrier, proceed as follows:

1. Lubricate cross shaft bearings and cups with light machine oil.
2. Install cross shaft assembly (minus high speed helical pinion) into carrier with cage or cover of hypoid side removed.
3. Install high speed pinion and set up in a press so that bearing retaining plate at hypoid side of cross shaft may be rested on a support at cover or cage opening.
4. Press bearing opposite hypoid gear onto shaft. Install bearing retaining plate and capscrews.
5. Install bearing cage or cover with shim pack on hypoid side of carrier. Replace capscrews and lock washers, then tighten to proper torque. *Should a press not be available, cross shaft bearing opposite gear side may be installed with a suitable driver placed against the inner race of bearing providing gear side of shaft is blocked up against bearing retainer. Do not drive or press bearings onto cross shaft with opposite bearing resting on cage or in cup. To do so will brinell cup and roller surfaces.*

On carriers permitting complete assembly of cross shaft before threading into carrier housing, proceed as follows:

1. Lubricate bearings and cups with light machine oil.
2. If bearing cover or cage on hypoid gear side has been removed, replace it using correct shim pack.
3. Thread cross shaft past differential bearing supports and position in bearing cup.
4. On carriers with front mounted shift units, position shift fork and install shift shaft. Align lock nut hole in fork with shaft indent and tighten lock screw and nut. Wire lock screw to fork.
5. Start bearing cage (side opposite hypoid gear) into carrier housing.
6. Tap bearing cage into position with soft mallet. Install capscrews.

Check Cross Shaft Bearing Preload

1. In checking cross shaft bearing preload torque, always rotate cross shaft and gear assembly several revolutions before checking preload to assure normal bearing contacts.
2. Lock low speed pinion and cross shaft with shift collar. Wrap a strong cord around pinion and pull on a horizontal line with a pound spring scale, Fig. 11. Assuming the pinion diameter to be 4", the radius would be 2", and with a pull of 7 pounds on the scale, the bearing preload would be 14 inch pounds of preload torque.
3. Read rotating pull (not starting pull). If preload torque is not within 5 to 15 inch pounds, add shims under cage (opposite hypoid gear) to decrease or remove shims to increase preload torque.

Install Pinion & Cage

1. Install pinion cage with original shim pack. Install capscrews and tighten.
2. Adjust hypoid gear backlash to .014-.020" (regardless of what markings might be etched on gear set) by transposing cross shaft bearing cage or cover shims, Fig. 12.
3. To move bevel gear away from pinion, remove shims from pack under cross shaft bearing cage on side opposite bevel gear and add shims of equal thickness to pack under cross shaft bearing cover or cage on bevel gear side. *Shims should be transposed in this manner to maintain established peload.*
4. To move bevel gear toward pinion, remove shims from pack under cross shaft bearing cover or cage on bevel gear side and add shims of equal thickness to pack under cross shaft bearing cage on side opposite bevel gear. *The actual backlash changes approximately .008" for each .010" movement of the gear.*
5. Check gear tooth contact for correct adjustment as outlined in the *Single Reduction Axle* section.

Fig. 12 Using dial indicator to determine gear lash

Fig. 13 Checking clearance of shift fork pads in shift collar with feeler gauge

Fig. 14 Differential pinion and side gear assembly

Install Shift Units

Power Actuated Side Mounted Type

1. Tap shift unit sleeve into carrier housing over original shim pack. Install lock washers and stud nuts.
2. Install new flange gasket. Hold shift fork in position. Align lock screw holes in shift shaft and slide shift unit and shaft into position.
3. Tighten fork screw and lock nut to 30-35 ft. lbs.
4. Install shift unit lock washers and stud nuts.
5. Check clearance of shift fork pads in shift collar with gauge, Fig. 13. Clearance should not be less than .010" on each side of fork in both high and low speed positions. *When checking clearance, shift collar must be flush with end face of spur pinion in both high and low speed positions.* Add or remove shims from pack under sleeve to obtain correct adjustment.
6. Check operation of shift unit. Ten pounds of air may be used to check vacuum type unit by applying air to opposite side of diaphragm, using vent opening on the single line shift unit.

Power Actuated, Front Mounted Type

1. Check bellcrank buttons and remove any scores at operating faces.
2. Place shift fork, collar and shift unit in high speed position. They must be in the same position to install shift unit.
3. Install new gasket and position shift unit with bellcrank in slot of shift shaft. Install lockwashers and capscrews. Do not disturb Allen set screw or travel positioning screw unless shift fork adjustments are needed. If adjustments are required, proceed as follows:
4. With fork and collar shifted to engage helical pinion next to hypoid gear, adjust Allen screw and lock nut in top of carrier so that fork is centered in collar groove within .005".
5. With fork and collar shifted to engage helical pinion away from hypoid gear, adjust hex head screw and lock nut in cross shaft cage so that fork is centered in collar groove within .005". When checking clearance, shift collar must be flush with end face of spur pinion in both high and low speed positions.
6. Check operation of shift unit in same manner as outlined for side mounted shift unit.

Assemble Differential

1. Join high and low speed spur gears to their respective case halves with bolts or rivets as desired. *When new spur gears or differential cases are installed, the case holes may require line reaming with the gear in order to assemble corect size bolts or rivets. When rivets are used they should be upset cold (not heated).*
2. Lubricate differential case inner walls and all parts with axle lubricant, Fig. 14.
3. Install thrust washer and side gear in one case half. Place spider with pinions and thrust washers in position. Install component side gear and thrust washer.
4. Align mating marks, position component case half and draw assembly together with four long bolts or capscrews equally spaced.
5. Check assembly for free rotation of differential gears and correct if necessary.
6. Install and tighten remaining bolts and secure with lock wire.
7. Press differential bearings squarely and firmly on case halves.

Install Bearing Cups In Carrier Leg Bores

1. Temporarily install bearing cups, threaded adjusting rings (where used) and bearing caps and tighten capscrews.
2. Bearing cups must be a hand push fit in bores otherwise bores must be re-worked with a scraper or emery cloth until a hand push fit is obtained. Use a blued bearing cup as a gauge and check fits as work progresses. This applies to all three types of carrier leg bores.
3. On carriers employing adjuster rings, if the rings cannot be turned by hand or with a maximum force of 10 lbs. applied at one end of a 2-ft. wrench (20 ft. lbs. torque) the O.D. should be slightly reduced with a fine mill file or use others that turn more freely. Be sure adjusting rings and threads are free from burrs or nicks.

Fig. 15 Checking differential bearing preload

Install Differential

1. After checking related parts, coat bearings with axle lubricant.
2. Place bearing cups over assembled bearing cones and position differential in carrier.
3. On the threaded adjusting ring type (see Fig. 2) insert rings and turn them hand tight against bearing cups. Position bearing caps in place.
4. On type with one threaded adjusting ring and one split ring (see Fig. 3) position split ring in groove of carrier leg and insert threaded adjusting ring on opposite side. Turn threaded ring hand tight against bearing cup. Install bearing caps.
5. With the split ring type (see Fig. 4) insert one ring in carrier leg groove. Move differential over so that face of bearing cup is held tightly against inserted ring. Install opposite split ring by tapping it into groove with a blunt end drift, tapping on lower I.D. of ring. Install bearing caps.
6. Install and tighten carrier leg screws.

Adjusting Differential Bearing Preload

Type With One or Two Threaded Rings

1. On units employing two threaded rings center helical gears in relation to helical pinions by means of the threaded rings.
2. Using a dial indicator as shown in Fig. 15 and starting with a definite amount of end play adjust differential bearings to zero end play. A pair of pinch bars may be used as shown. Rotate assembly several revolutions each time adjusting rings are moved before checking end play to assure normal bearing contact.
3. Tighten adjusting rings 1¾ to 2½ notches (total of both rings) to correctly preload bearings.
4. Install ring locks and capscrews (where used) and install lock wire.

Type Employing Two Split Rings

1. Temporarily install differential in carrier and center between carrier leg grooves.
2. Insert thin split rings making certain that there is clearance between bearing cup faces and rings (do not install bearing caps).
3. Measure end play as shown in Fig. 15.
4. Remove and measure thickness of thin rings. To the total thickness of the two thin rings add the end play figure plus another .017 to .022″ to obtain total thickness of the two thicker rings required to obtain proper bearing preload. Hardened split rings are ground in increments of .005″.
4. When proper bearing preload has been established complete the assembly of the differential. Install unit in axle housing in reverse order of removal.

Single Reduction Thru-Drive Tandem Axles

DESCRIPTION

This type drive, Fig. 1, utilizes a modified conventional single reduction axle for the forward rear axle and a conventional single reduction axle for the rearward axle. A power divider or inter-axle differential is mounted integrally with the forward axle. This type of drive permits a tandem hook-up with a minimum of angles in the drive line.

The pinion bearing preload is adjusted and maintained by a hardened precision spacer between the inner and outer tapered bearings. The differential bearing preload is adjusted and maintained by threaded adjusting rings located in the carrier legs and caps.

The inter-axle differential may be engaged or disengaged by a power actuated shift unit which moves a sliding collar on the through shaft splines. The shift unit is controlled by a selector switch or lever within the cab of the vehicle and may be engaged or disengaged under any normal operating conditions.

The inter-axle differential when engaged (unlocked) divides the engine torque between the forward and rearward axles; when disengaged (locked) it converts the two axles to a through drive type tandem.

DISASSEMBLE

Remove Unit From Housing

1. Disconnect forward and rear propeller shafts.
2. Drain lubricant from axle housing and inter-axle differential.
3. Remove axle shafts as outlined for standard single reduction axles.
4. Remove shift shaft housing assembly.
5. Disassemble and remove shift lever attaching nut, button, lever, cup and spring. The body fit bolt should not be removed.
6. Remove thru-shaft, cage and yoke, Fig. 4. To free cage from case bore it may be necessary to tap yoke with a soft mallet. While thru-shaft assembly is being threaded out, the sliding clutch must be eased along the shaft at the shift lever opening. When thru-shaft clears opening, the clutch may be lifted out.

Fig. 1 Type 3 single reduction tandem drive forward axle. This unit differs from Type 2 in that it employs splines instead of dog teeth on the inter-axle differential, as shown in Figs. 2 and 3. Type 1 is similar to Type 2 except that the impeller (oil scoop), oil baffles, etc. used in Type 2 are not employed in Type 1

Fig. 2 Types 1 and 2 inter-axle differential shift mechanism

Fig. 3 Type 3 inter-axle differential shifting mechanism

Fig. 4 Removing thru-shaft and cage

Fig. 5 Removing thru-shaft radial bearing

7. Remove carrier from axle housing in same manner outlined for the standard single reduction axle.

Disassemble Thru-Shaft

1. After removing nut, use puller to remove yoke.
2. Press thru-shaft from cage, using a suitable sleeve against bearing inner race.
3. Remove cage snap ring, Fig. 5. Then tap radial bearing out of bore from seal end. If seal is damaged or worn, press out with suitable sleeve. If seal is in good condition, do not disturb.

Disassemble Inter-Axle Differential

1. Separate inter-axle differential and adapter case from carrier case, Fig. 6.
2. Unfasten and lift inter-axle differential from adapter case, Fig. 7.
3. Remove input shaft flange or yoke nut.
4. Press inter-axle differential from cover.
5. If original identification marks are not clear, mark differential case halves with a punch for correct alignment on reassembly.
6. Disassemble case halves and remove differential components.
7. On Types 1 and 2, remove radial bearings from differential case halves with a suitable puller, pulling against inner race of bearing. On Type 3, do not remove radial bearing from case unless replacement is necessary.
8. To disassemble adapter case, tap upper drive gear back until gear touches case. Remove spacer and snap ring from bearing outer race. Tap drive gear out of adapter case, Fig. 9. Do not remove radial bearing from gear hub unless replacement is necessary. If necessary, fold back tab locks and remove hub snap ring. Then remove bearing with suitable puller.
9. To disassemble idler gear, remove nut and spacing washer. Remove shaft and slide out gear and bearing. Remove tapered bearings and tap out cups and related parts, Fig. 10.

Main Diff. Case, Ring Gear & Drive Pinion

Service procedures on these components are the same as outlined for the standard single reduction axle.

REASSEMBLE

Main Differential Case, Ring Gear & Drive Pinion

Assembly procedure, adjusting pinion bearing and differential bearing preloads, checking ring gear and pinion backlash are the same as described for the standard single reduction axles. Complete the assembly and adjustment of these parts, then proceed with the adapter case and inter-axle as follows:

Fig. 6 Lifting power divider from differential carrier

Fig. 7 Separating power divider cover from case

Fig. 8 Inter-axle differential parts

Assemble Adapter Case

1. Install snap ring and press idler gear inner bearing cup squarely against snap ring.
2. Insert idler gear cup spacing sleeve against opposite side of snap ring.
3. Press idler gear outer bearing cup squarely against spacing sleeve.
4. Position idler gear inner and outer bearings into cups with hardened bearing spacer (or combination of two spacers) between them. *Some of the Type 1 drive units do not incorporate the idler bearing spacer or the*

Fig. 9 Drive gear and bearing removed from case

idler shaft "O" ring. These parts should be added to any of the units that do not have them.

5. Slide complete assembly through adapter case drive pinion opening. *On Types 1 and 2, position assembly so that bearings are aligned with adapter case shaft hole. On Type 3, temporarily push the assembly to the far side of the pocket and proceed to install upper drive gear assembly.*
6. On Types 1 and 2, tap idler shaft through idler gear so that inner bearing is squarely against idler shaft shoulder.

Idler Shaft Bearing Adjustment

On Types 1 and 2, this adjustment is made before assembling the upper drive gear. On Type 3, first assemble the upper drive gear, then make the adjustment as follows:

1. Hold adapter case and idler gear securely in a vise with jaws clamped on flatted end of idler shaft.
2. Install washer and nut and torque nut from 350 to 400 lb. ft.
3. Measure idler shaft bearin end play with a dial indicator mounted to adapter case proper with stem set against idler gear face. End play should be .001"-.005".
4. If not within these limits, use a thinner or thicker spacer or combination of two spacers as required.
5. After proper end play has been established, remove washer and nut. Insert "O" ring and reinstall washer and nut. Tighten nut from 350 to 400 lb. ft. and install cotter key.

Assemble Upper Drive Gear

On Type 3, this gear is assembled before adjusting idler shaft bearing, the procedure for all types being as follows:

1. If rear bearing has been removed for replacement, press new bearing on hub using a suitable sleeve against bearing inner race.
2. Install tabbed lock ring and hub snap ring.
3. With radial bearing outer race snap ring removed, position drive gear in case. Tap assembly through bore until gear touches wall of case.
4. Install radial bearing outer race snap ring in the groove. Tap gear back so that snap ring seats in recess in case.
5. On Types 1 and 2, install spacer over outer race of bearing against snap ring.
6. On Type 3, position spacer over bearing with flat toward pinion cage bore. Position idler assembly so that bearings are lined up with idler shaft hole. Tap idler shaft through gear so that inner bearing is squarely against idler shaft shoulder.

Assemble Inter-Axle Differential

1. Lubricate differential case walls and all component parts with axle lubricant.
2. Position thrust washer and rear side gear into rear case half.
3. Place spider with pinions and thrust washers into position.
4. Install forward side gear and thrust washer.
5. Align mating marks, position forward case half and draw together with case capscrews. Types 2 and 3 employ an impeller over forward case half.
6. Tighten case capscrews to correct torque.
7. Check for free rotation of gears and correct if necessary.
8. On Types 1 and 2, install forward radial bearing spacer and press on forward and rear radial bearings.

Fig. 10 Idler gear components

Install Inter-Axle Differential

Types 1 and 2

1. If snap ring was removed, reinstall in nose of cover.
2. Install cover-to-case gasket. Position cover over inter-axle differential and tap down with a sleeve until forward radial bearing seats against snap ring.
3. Position cover and differential over upper drive gear hub and tap down until rear radial bearing snap ring seats in adapter case recess. It may be necessary to rotate the assembly slightly to line up the dog teeth.
4. Install capscrews and lockwashers and draw cover and adapter case together. Tighten capscrews to specified torque.

REPLACEMENT—DIFFERENTIAL GEAR TO CASE BOLTS

TANDEM MODEL CARRIER	SERVICE BOLT	NUT	LOCKWIRE	ORIGINAL RIVET	SPOTFACE DIAMETER	TORQUE — LB. FT. MIN.	TORQUE — LB. FT. MAX.
DHD —	15X-775	N-28-1	LW-1610	RV-7812	1 1/8"	92	102
FHD —	15X-775	N-28-1	LW-1610	RV-7812	1 1/8"	92	102
†LHD —	15X-666	N-29-1	LW-1610	RV-7913	1 3/8"	130	145
†QHD —	15X-666	N-29-1	LW-1610	RV-7913	1 3/8"	130	145
‡LHD —	15X-786	N-210-1	LW-1610	RV-71014	1 3/8"	185	205
‡QHD —	15X-786	N-210-1	LW-1610	RV-71014	1 3/8"	185	205

† Original production had 9/16" rivets and require 9/16" bolts and nuts for service.

‡ Current production has 5/8" rivets and require 5/8" bolts and nuts for service.

Service will no longer stock the original gears incorporating the 9/16" holes.

In case of current gear replacement with original cases it will be necessary to line ream the original cases to .625" to accommodate the larger bolts or rivets.

Torques given apply to parts coated with machine oil; for dry (or "as rec'd") parts increase torques 10%; for parts coated with multi-purpose gear oil decrease torques 10%. Nuts on studs to use same torque as for driving the stud.

Fig. 11 Torque specifications for single reduction thru-drive tandem axles

5. Install cover oil seal with suitable driver.

Type 3

1. If cover was disassembled, install forward radial bearing and snap ring.
2. Install spacer on input shaft.
3. Position cover over input shaft and tap down until radial bearing seats against spacer.
4. Install gasket and position cover and differential over upper drive gear hub. Tap assembly into position. It will be necessary to line up the splines of the drive gear with those of the side gear.
5. Install capscrews and lockwashers and torque to specifications.
6. Install cover oil seal with suitable driver.

Assemble Adapter Case & Inter-Axle Differential to Carrier

1. Mount carrier in stand in upright position. Install gasket and place adapter case over carrier. The idler shaft flat must be lined up with corresponding flat in carrier.
2. Install lockwashers and capscrews and torque to specifications.

Final Assembly

1. Install carrier in axle housing in a manner outlined for standard single reduction axles.
2. Install thru-shaft rear radial bearing into cage and lock in place with snap ring.
3. Press bearing and cage on splined end of thru-shaft with suitable sleeve.
4. Install thru-shaft cage oil seal with suitable driver.
5. Enter thru-shaft and cage with new cage gasket into cage bore at rear of axle housing until forward end of shaft is even with shift lever opening.
6. Install sliding clutch collar over forward end of shaft through shift housing opening. Ease shaft into forward side gear of inter-axle differential, while at the same time passing clutch collar onto collar splines.
7. Install thru-shaft cage capscrews and washers and torque to specifications.
8. Install over shift lever bolt the shift lever spring, cup and lever. Lever inner yoke must be properly located in collar groove at this time. Install shift lever button and nut. Tighten nut securely and install cotter key.
9. Position gasket and shift housing against drive unit, making sure that shift lever yoke is properly located in shift collar groove.
10. Install shift housing capscrews and torque to specifications.

Adjusting Shift Shaft

1. Adjust positioning screw at rear of shift housing as follows: With shift shaft moved back its full travel, locking the inter-axle differential, turn adjusting screw in until end of screw touches end of shift shaft.
2. From this point proceed 1 to 1¼ turn more and lock adjusting screw with jam nut. This will allow approximately .012" clearance between the yoke and groove of collar and thus eliminate yoke and collar wear. The shift collar provides a definite stop against housing wall when shifted in the opposite direction.

Install Thru-Shaft Yoke

1. Install yoke on splines with suitable sleeve. Install washer and nut.
2. By using a holder on yoke, tighten yoke nut to proper torque and install cotter key.

Double Reduction Thru-Drive Tandem Axles

Fig. 1 Timken double reduction, top-mounted thru-drive axles. Both hypoid and spiral bevel gears are used in the first reduction. Either straight spur or helical gears are used in the second reduction

In these units, Fig. 1, tapered roller bearings support the forward and rear ends of the thru-shaft and pinion assembly of spiral bevel gear units. Bearing preload is adjusted and maintained by shim packs between carrier machined surfaces and bearing covers. Yokes or flanges, held in place by thru-shaft nuts, press against the bearing cones or spiral bevel pinion splined to thru-shaft.

The thru-shafts of hypoid gear drive units are supported at the forward end by tapered roller bearings in a cage and at the rear end by a straight roller bearing. Pinion bearing preload is adjusted and maintained by a hardened precision spacer between inner and outer tapered bearings which are held in place on the thru-shaft by separate thru-shaft nuts.

Hypoid gear top-mounted forward drive units may be equipped with an inter-axle differential of the planetary type which divides engine torque between the forward and rear axles. The differential is equipped with a lock-up device which converts the tandem assembly to a thru-drive type tandem. The lock-up is actuated by an air chamber and is controlled in the vehicle cab. It can be engaged and disengaged under all normal operating conditions. Fig. 2 illustrates the early design shift unit, while Fig. 3 is the current design.

DISASSEMBLE

During the disassembly process, be sure to keep any shims found with parts intact and identified so that when reassembling, adjustment of unit involved will be facilitated.

1. Drain axle and inter-axle differential housings.
2. Remove axle shafts and carrier from housing.
3. Match mark one differential carrier leg and bearing cap for identification on reassembly.

4. Lift out differential. Before dismantling differential, match mark case halves for proper alignment on reassembly.
5. Remove pinion and thru-shaft on models not equipped with inter-axle differential.
6. If inter-axle differential is used, remove shift unit.
7. Remove inter-axle differential bearing and cover assembly. Hoist inter-axle differential out with a chain fall.
8. Disassemble thru shaft.
9. Disassemble inter-axle differential.
10. Disassemble cross shaft.

REASSEMBLY

Service Note

The thru-shaft, pinion and bearing assembly of the spiral bevel type drive units must be installed in the carrier before the cross shaft assembly is installed. This permits determining the thickness of shim packs that control pinion bearing preload without interference of the cross shaft assembly. The thru-shaft assembly is then removed and the cross shaft assembly installed. Cross shaft bearing preload must be established at this time before final installation of the thru-shaft assembly with previously determined shim packs.

The cross shaft assembly of hypoid gear units must be installed in the carrier first so cross shaft bearing preload can be established without interference of the thru-shaft and pinion assembly. The thru-shaft, pinion, bearing and cage may be assembled at the bench and then installed in the carrier.

Assemble Spiral Bevel Pinion & Thru-Shaft

1. Press tapered bearing on pinion.
2. Coat pinion and thru-shaft splines with heavy grease and press parts together. *Press parts together about ¼" to ⅜", then relieve press pressure to permit them to realign themselves to prevent distortion and damage. Continue the pressing operation until parts are correctly assembled.*
3. Install pinion, bearing and thru-shaft in drive unit. Install pinion bearing cup with suitable sleeve, Fig. 4.
4. Install spacer (if used) over splined end of thru-shaft and tighten nut on spacer end of thru-shaft.
5. Coat seal with non-hardening sealing compound and install in bearing covers. Lubricate sealing element of seal.
6. Install bearing cover and seal assembly (where used) and original shim pack over splined end of thru-shaft. Tighten cover nuts.
7. Install bearing opposite pinion firmly against shaft shoulder.
8. Install bearing cup in drive unit, rotating shaft to position all bearing rollers.
9. Install bearing cover and seal over original shim pack and tighten stud nuts.

Fig. 2 Shift unit assembly (early models)

Fig. 3 Shift unit assembly (later models)

Fig. 4 Installing pinion, bearing and thru-shaft assembly with sleeve shown

Fig. 5 Measuring thru-shaft bearing preload

Measuring Thru-Shaft Bearing Preload

1. As shown in Fig. 5, wrap strong cord around thru-shaft and pull on a horizontal line with a pound scale.
2. The preload specification for tapered roller bearings at opposite ends of thru-shaft is zero thru-shaft end play to 5 inch pounds torque.
3. Alter shim pack under bearing cover at end opposite pinion so there is no thru-shaft end play when measured with a dial indicator and so bearing preload torque does not exceed 5 inch pounds.
4. For example, assuming thru-shaft diameter is 1½", the radius is ¾" and with 4 pounds pull on scale, preload torque is 3 inch pounds.
5. Read rotating pounds pull (not starting pull). If preload torque is not within specified limits, add shims under bearing cover at end opposite pinion to decrease torque or remove shims at same location to increase preload torque.
6. Complete bearing adjustments before installing flanges or yokes.
7. Remove thru-shaft. Keep both shim pack with their respective covers to maintain established bearing preload.

Assemble Cross Shafts

Check I.D. of sleeve and O.D. of radial bearing and replace either or both of these parts if there is more than .006" clearance between them. When new, these parts have a clearance of .0024" to .004". The radial bearing must be free to float in the sleeve.

Check the I.D. of the bearing bore on older drive units that do not have replaceable sleeves. If the I.D. is more than .006" larger than the bearing O.D., replace carrier and cap assembly with the newer type carrier and cap that incorporates replaceable sleeves.

If sleeve is to be replaced, press new sleeve firmly against housing shoulder. Drill hole for lock screw and remove burrs from sleeve. Install and tighten lock securely or install pin and stake in place.

Assemble Type 1 Cross Shaft

Gear Journal Fit to Cross Shaft

1. Install 6 studs at cross shaft flange. Assemble radial bearing on gear hub with large radius of bearing inner race toward back of gear.
2. Install bearing washer on gear hub against bearing with chamfer of spacer away from bearing. Install spacers with I.D. chamfer so chamfer is next to radius at root of pinion teeth. *A large flat washer is used at this location when O.D. of pinion teeth is smaller than I.D. of bearing.*
3. Coat I.D. of gear with heavy grease. Install gear, bearing and spacer assembly in drive unit sleeve and block up to hold in place.
4. Inspect entering end of cross shaft and remove any nicks or burrs. Coat O.D. of shaft and I.D. of gear with heavy grease.

5. Position housing in press with thru-shaft chamber down and gear supported on suitable sleeve.
6. Align key in cross shaft with keyway in gear hub and press shaft firmly against gear, bearing and spacer. *Continue pressing to exert 10 to 20 tons pressure in excess of that required for secure assembly.*
7. Install tapered bearing cage original shim pack (which controls gear position) over cross shaft cage studs.
8. Apply graphite lubricant to cross shaft tapered bearing journal and assemble inner and outer bearings, using suitable sleeves.
9. Install cage and bearing assembly in drive unit, pressing against outer bearing cone with suitable sleeve. Be sure oil holes in cage are aligned with oil holes in drive unit.
10. Assemble bearing retainer plate with two capscrews and secure with lock wire.
11. Install bearing cage cover over original shim pack (which control tapered bearing preload) over studs next to cage flange.
12. Assemble bearing cage cover, lock washers and stud nuts.
13. Wrap a strong cord around spur pinion, Fig. 6, and pull on a horizontal line on pound scale to measure cross shaft bearing preload torque. Proper perload torque is 5 to 15 inch pounds, which is equivalent to 2½ to 7½ pounds pull on scale.
14. Read rotating pull (not starting pull). If torque is not within limits, add shims between cover and cage to decrease, or remove shims to increase torque.
15. Install thru-shaft and pinion.
16. Adjust pinion and gear to secure correct gear tooth contact and backlash.

Assemble Type 2 Cross Shaft

Gear Splined to Hub, Hub Keyed to Cross Shaft

1. Apply graphite to cross shaft tapered bearing journal. Press inner bearing firmly against shaft shoulder with suitable sleeve.
2. Assemble gear to hub, aligning 6 gear-to-hub capscrew holes. Tighten screws securely.
3. Position drive unit on press bed with thru-shaft chamber up, and install radial bearing in drive unit sleeve. Large radius of bearing inner race must be toward bevel gear.
4. Support inner race of radial bearing with sleeve and press gear and hub assembly into bearing.
5. Turn drive unit over in press with thru-shaft chamber down, and support gear, hub and bearing assembly on sleeve with notches in end that fit over capscrew heads.
6. Inspect entering end of cross shaft and remove any nicks or burrs. Coat O.D. of shaft with heavy grease.
7. Align keyway in hub with key in cross shaft and press shaft and inner tapered bearing assembly firmly against hub.
8. Remove drive unit from press and install 6 cross shaft cage studs.

Fig. 6 Measuring Type 1 cross shaft bearing preload

Fig. 7 Measuring Type 2 cross shaft bearing preload

Fig. 8 Install inner bearing on Type 3 cross shaft, using wood block as shown

9. If tapered bearing cup has been removed from cross shaft cage, reassemble in press using sleeve to install cup firmly against cage shoulder.
10. Install original shim pack (which controls gear backlash) over studs, and cross shaft cage over shim pack, *aligning oil holes in cage with oil holes in drive unit.*
11. Install outer tapered bearing using suitable sleeve.
12. Install cross shaft bearing adjusting nut. Tighten nut as cross shaft is revolved to position all bearing rollers.
13. Measure cross shaft bearing preload torque by wrapping strong cord around spur pinion, Fig. 7, and pull on a horizontal line with pound scale. Preload torque should be 5 to 15 inch pounds which is equivalent to 2½ to 7½ pounds pull on scale.
14. Read rotating pull (not starting pull). If torque is not within limits, tighten bearing adjusting nut to increase, or loosen nut to decrease torque. Back off adjusting nut ¼ to ⅓ turn. Then install nut lock, flat washer and jam nut. Tighten jam nut to 500 ft. lbs. Recheck bearing preload. When correct, bend flat washer over jam nut.
15. Install thru-shaft and pinion.
16. Adjust pinion and gear to secure correct gear tooth contact and backlash.
17. Remove stud nuts and flat washers. Install bearing cage cover gasket, cover, stud nuts and lock washers.

Assemble Type 3 Cross Shaft

Gear Splined to Cross Shaft

1. Install radial bearing in drive unit with large radius of bearing inner race toward bevel gear.
2. Position drive unit in press with thru-shaft chamber up. Coat O.D. of shaft with heavy grease and press parts together about ¼″ to ⅜″. Then release press pressure to permit parts to align themselves to prevent distortion and damage. Continue pressing operation until parts are properly assembled.
3. Align gear and cross shaft capscrew holes and assemble gear to shaft. Torque capscrews to 65-85 ft. lbs.
4. Block up gear as shown in Fig. 8. Apply graphite lubricant to cross shaft tapered bearing journal. Install inner bearing firmly against shaft shoulder with suitable sleeve.
5. If tapered bearing cup has been removed, press cup firmly against shaft shoulder.
6. Install original shim pack (which controls gear backlash) over cross shaft cage studs, and cage over shim pack, aligning oil holes in cage with oil holes in drive unit. Install 4 evenly spaced nuts over thick flat washers to hold assembly in place. Tighten nuts securely.
7. Install outer tapered cross shaft bearing with suitable sleeve.
8. Install bearing adjusting nut. Tighten nut as cross shaft is being revolved to correctly position all bearing rollers.
9. Measure cross shaft bearing preload. Wrap strong cord around spur pinion, Fig. 7, and pull on horizontal line with pound scale. Preload torque is 5 to 15 inch pounds which is equivalent to 2½ to 7½ pounds pull on scale. If preload is not within limits, tighten bearing adjusting nut

Fig. 9 Measuring pinion bearing preload on hypoid gear unit

Fig. 10 Position of pinion locking components on hypoid gear units

Fig. 11 Assemble rear gear against insert with locking teeth up

to increase, or loosen nut to decrease preload torque.

10. Back off adjusting nut ¼ to ⅓ turn. Install nut lock, flat washer and jam nut. Tighten jam nut to 500 ft. lbs. Recheck bearing preload. When correct, bend flat washer over jam nut.
11. Install gear cover spacers, cover and 3 capscrews. Install pinion and thru-shaft. Adjust pinion and gear for correct gear backlash and tooth contact.
12. Remove stud nuts and flat washers. Install cage cover gasket, cover, nuts and lockwashers.

Install Hypoid Pinion & Thru-Shaft

1. Press pinion bearing cups in cage firmly against shoulder.
2. Coat thru-shaft O.D. and rear bearing inner race I.D. with heavy grease. *Press rear bearing inner race against rear shoulder of thru-shaft of forward carriers and rear carriers that have double splined end shafts. On rear carriers with short single end thru-shafts, install rear bearing inner race retainer, then press race in place and install outer retainer.*
3. Coat pinion and thru-shaft splines with heavy grease. Begin assembly operation in a press and press parts together ¼″ to ⅜″. Then relieve press pressure to permit parts to realign themselves to prevent distortion and damage. Continue pressing operation until parts are correctly assembled.
4. Lubricate all bearing journals with a few drops of engine oil and press inner pinion bearing firmly in place.
5. Position original bearing spacer next to bearing, being sure O.D. chamfer is toward outer bearing.
6. Install cage and cup and outer bearing. Press bearing firmly against selective spacer with suitable sleeve, rotating cage to assure normal bearing contact.
7. Measure pinion bearing preload torque while in press under 9 tons pressure. Wrap strong cord around cage pilot, Fig. 9, and pull on a horizontal line with a pound scale. The preload torque should be 5 to 15 inch lbs. which is equivalent to 2½ to 7½ pounds pull on scale. Use a thinner spacer to increase or a thicker spacer to decrease preload.
8. Remove assembly from press and install and tighten inner nut. Assemble as shown in Fig. 10. When properly tightened, bend lock washer over nut flat.
9. Install thru-shaft rear bearing with suitable sleeve. Check position in forward carrier with cover and seal assembly. In rear carriers with long thru-shaft (both ends splined) check position with cast end cover. In rear carriers with short thru-shaft, use large bearing spacer as a gauge.
10. Loosely install two guide studs in cage capscrew holes to aid reassembly. Position original shim pack over studs so oil holes are aligned. Carefully tap pinion, cage and thru-shaft in place.
11. Install and tighten 4 capscrews over flat washers to hold pinion cage firmly in place while checking hypoid tooth contact. Alter shim packs under cross shaft bearing cage to secure correct tooth contact.
12. Coat pinion oil seal with non-hardening sealing compound and install in cover. Lubricate sealing element.
13. Remove 4 capscrews and guide studs. Coat outer machined surface of cage and inside of cover with gasket cement. Install new gasket on cage flange.
14. Install cover and seal. Apply gasket cement to all covers and mating surfaces and install covers.
15. On rear drive units with thru-shafts splined at both ends, assemble parts as follows: Narrow spacer next to rear bearing inner race. Wide spacer next to narrow spacer. Nut washer, then rear nut.
16. Install forward yokes or flanges. Install narrow spacer at rear end of forward carrier thru-shaft, then yoke or flange.

Assemble Inter-Axle Differential

Assemble inter-axle differential as shown in Figs. 11 to 25 . Then proceed with the assembly as follows:

1. Position new gasket on cover and install bearing and seal retainer.
2. Carefully inspect completed assembly to be sure capscrew ends do not interfere with shift yoke or shift rings.
3. Install yoke or flange, washer and nut.

Fig. 12 Assemble yoke to shift collar

Fig. 13 Assemble spacer over collar yoke

Fig. 14 Install retainer in shift collar groove

Fig. 15 Position stamped collar retainer cover over retainer

Fig. 16 Assemble shift shafts in collar and yoke and install snap rings in grooves as indicated

Fig. 17 Install pinions and shift yoke, collar and shaft assemblies, mating internal teeth of collar with teeth of rear side gear

Fig. 18 Install forward differential gear. Turn gears to be sure all parts are correctly assembled and free-moving. Install forward thrust washer

Fig. 19 Install forward case half, being sure to align match marks on case halves

Fig. 20 Install pinion shaft locks

Fig. 21 Fasten case halves together. Check assembly for free movement by rotating pinions

Assemble Hypoid Pinion & Quill

1. Press pinion bearing cups against housing shoulder. Assemble rear bearing inner race inner retainer. Coat quill O.D. and race I.D with heavy grease and press race in place. Install outer retainer.
2. Lubricate all bearing journals with a few drops of engine oil and press inner bearing on pinion and quill assembly.
3. Install original spacer on inner bearing with O.D. chamfer of spacer toward outer (forward) bearing.
4. Position housing and cup assembly on pinion. Press bearing firmly against selective spacer with suitable sleeve, rotating housing to assure normal bearing contact.
5. Measure pinion bearing preload while in press under 9 tons pressure. Wrap strong cord around housing pilot, Fig. 26, and pull on a horizontal line with a pound scale. Preload should be 5 to 15 inch pounds which is equivalent to 2½ to 7½ pounds pull on scale.
6. Use a thinner spacer to increase or a thicker spacer to decrease preload. Tighten adjusting nut and recheck preload.
7. Install pinion quill rear bearing in carrier with suitable sleeve. Check location with thru-shaft ball bearing retainer.
8. Loosely install 2 guide studs in carrier if capscrews are used to hold

Fig. 22 Install shift collar. Tighten nuts to 65-85 ft. lbs. Be sure shift collar and shafts work up and down freely. If necessary rap assembly at several points on case to free up parts

Fig. 23 Install ball bearing in housing cover.

Fig. 24 Assemble cover and bearing assembly to differential. Use a small sleeve over input shaft against bearing inner race. Rotate cover to be sure it clears differential

housing in place. Position original shim pack over studs so oil holes are aligned. Carefully tap pinion, housing and gear assembly in place.

9. Install 4 equally spaced capscrews or stud nuts to hold assembly in place while checking hypoid gear tooth contact. Alter shim pack under cross shaft bearing cage and inter-axle differential housing to secure correct tooth contact.
10. Install remaining capscrews or stud nuts and secure with lock wire.

Install Inter-Axle Differential

1. Turn carrier so pinion and quill assembly is in vertical position and loosely install 3 guide studs in differential housing. Position gasket in place and install differential and cover. Revolve differential back and forth to engage splines of pinion with rear gear. Install capscrews.
2. Revolve differential to be sure it is free turning. If not, remove it and inspect parts.
3. Check position of oil scoop for interference at helix baffle at left inside housing of early models.
4. Install and tighten 2 capscrews at shift lever housing. Secure with lock wire.

Install Shift Unit Housing

1. Hold shift unit in vise and install push rod in housing and fork, Fig. 27. Be sure round button of fork faces front. Assemble push rod in place with sleeve.
2. Place copper gasket over end of push rod and install diaphragm assembly. Hold push rod with screwdriver while starting nut over lock washer. Be sure flats of push rod fit in slot of diaphragm insert as nut is tightened. Tighten nut to 4-6 ft. lbs. Install shift unit cover plug.
3. Attach assembly to cover with 2 capscrews over lock washers. Install 2 tapered dowels, special lock washers and stud nuts.

Adjust Shift Fork (Late Models)

This adjustment is for later models without shift shaft springs that have both forward and rear adjusting screws. Always check shift fork location with feeler gauge, Fig. 28, to be sure there is .010″ clearance (minimum) at guide rings or groove.

Lockout Disengaged, Forward Adjusting Screw

1. Back off adjusting screw lock nut so screw is free turning.
2. Shift assembly to disengaged position with power chamber.
3. Turn in adjusting screw until it is finger-tight against fork.
4. Turn in screw ½ revolution more to center fork in groove.
5. Tighten lock nut.

Lockout Engaged, Rear Adjusting Screw

1. Back off adjusting screw lock nut so screw is free turning.
2. Shift assembly to engaged position with power chamber. Be sure shift collar is fully engaged with rear gear.
3. Turn in screw until it is finger-tight against push rod.
4. Turn in screw ½ revolution more to center fork in groove. Tighten lock nut.

Adjust Shift Fork (Early Models)

This adjustment is for early models that have shift shaft springs and only a forward adjusting screw. With lockout disengaged, adjust as follows:

Fig. 25 Install retainer with slot indicated up, aligned with oil hole in cover

Fig. 26 Measuring pinion bearing preload

Fig. 27 Installing shift unit push rod

Fig. 28 Adjusting shift fork, using feeler gauge

Fig. 30 Torque specifications for double reduction thru-drive tandem axles. Torques given apply to parts coated with machine oil. For dry (or "as received") parts increase torques 10%. For parts coated with multi-purpose gear oil decrease torques 10%. Nuts on studs to use same torque as for driving the stud

1. Back off adjusting screw lock nut.
2. Turn screw in finger-tight against fork. This forces fork against inner guide ring.
3. Back off screw 1/2 revolution to center fork between guide rings.
4. Tighten lock nut.

Install Thru-Shaft

1. Coat seal body and seat with non-hardening sealing compound and install in cover with suitable sleeve. Lubricate sealing element.
2. Install thru-shaft ball bearing firmly against shaft shoulder and assemble shaft and bearing in retainer.
3. Position new gasket over studs and install shaft assembly. Be sure thru-shaft splines mesh with forward gear of inter-axle differential. Do not force in place.
4. Install cover and seal with new gasket. Alternately tighten 4 evenly spaced stud nuts to draw assembly in place and correctly position pinion quill rear bearing. Install and tighten stud nuts.
5. Install thru-shaft yoke or flange.

Tooth Contact & Gear Backlash

Tooth contact may be checked as outlined in the *Single Reduction Axle* section. Spiral bevel gear first reduction units have shim packs between the forward and rear thru-shaft tapered bearing covers and the carrier to control pinion position. Hypoid gear first reduction units have a single shim pack between the pinion cage and carrier or inter-axle differential housing and carrier to control pinion position. A shim pack between the cross shaft bearing cage flange and carrier controls the position of the first reduction spiral bevel or hypoid gear in all top-mounted double reduction drive units.

Set backlash to the amount specified on gear O.D. When backlash is not specified on gear set to .006-.012".

Be sure all bearing preloads are within specified limits before checking tooth contacts. Transpose equal amounts of shims between front and rear pinion bearing covers of spiral bevel drive units to maintain correct bearing preload while adjusting tooth contact. Add or remove shims between pinion cage or inter-axle differential housing of hypoid drive gear units to alter pinion location. Change the location of spiral bevel or hypoid gear by altering the thickness of the shim pack between the cross shaft bearing cage flange and carrier.

Fig. 29 Installing split ring

In hypoid gearing the actual backlash changes .008″ for each .010″ movement of the gear. In spiral bevel gearing, the actual backlash changes .007″ for each .010″ movement of the gear.

Install Axle Differential

1. Press differential bearings firmly against case shoulders. Coat inside of case and all differential parts with rear axle lubricant.
2. Assemble differential case half and gear. Install side gear thrust washers, side gears and pinion gears, thrust washers and spider.
3. Note case alignment marks and assemble opposite case half. Hold assembly together with 4 bolts and nuts and check for free rotation of parts.
4. Install remaining case bolts so heads are locked by machined relief in case half. Be sure case halves are assembled to gear so there is adequate nut clearance. Check clearance in carrier before completing assembly.
5. When a new gear or differential case is installed, the case holes must be line-reamed with the gear in order to assemble the parts, using the correct size rivets or bolts. Align case halves and hold together with 4 bolts. Line ream the holes and clean parts before assembly.

Install Differential Bearing Cups

1. Temporarily install bearing cups, threaded adjusting rings (when used) and bearing caps. Tighten capscrews securely.
2. Bearing cups must be a hand push fit in bores, otherwise bores must be re-worked with a scraper or emery cloth until a hand push fit is obtained. Use a blued bearing cup as a gauge and check fit as work progresses.

Bearings With Two Threaded Adjusting Nuts

1. Apply rear axle lubricant to bearing cups and cones. Position cups over cones and install in carrier.
2. Insert differential bearing adjusting nuts and turn hand tight against bearing cups.
3. Install bearing caps. Install and tighten stud nuts or capscrews.
4. Alternately loosen one adjusting nut and tighten the other while turning the differential to assure normal bearing contact and to keep bearing cups straight in the bores.
5. With a dial gauge, establish zero end play. Then tighten adjusting nuts 1¾ to 2½ notches (total for both nuts) tight to correctly preload bearings.
6. Install adjusting nut locks and capscrews.

Type With Two Split Rings

1. With differential and bearings installed, insert thin split rings, making certain that there is clearance between bearing cup faces and rings (do not install bearing caps).
2. With a dial indicator, measure end play of differential by shifting assembly back and forth between rings with a pair of small pinch bars placed between carrier legs and spur gears.
3. Remove and measure thickness of rings. To the total thickness of the 2 thin rings add the end play figure plus another .017″ to .022″ to obtain the total thickness of the 2 thicker rings required to obtain proper bearing preload. Split rings are available in increments of .005″.
4. Insert one split ring in carrier leg groove. Move differential over so that face of bearing cup is held tightly against inserted ring. Rings should be positioned in carrier leg grooves so that split portion will locate in center of cap.
5. Install opposite split ring by tapping it into the carrier leg, Fig. 29, tapping on I.D. of ring opposite split portion.
6. Install differential bearing caps and install capscrews.

Timken Worm Drive Axle

This type axle, Fig. 1, incorporates a forged, ground and polished worm of alloy steel and a worm wheel compounded of special phosphor-bronze. Worm drive units are usually incorporated in tandem drive vehicles where high engine horsepower is required to move heavy loads and where chassis design may be a factor limiting drive unit size.

Remove Drive Unit from Housing

1. Disconnect U-joints at ends of worm shafts. Remove plug at bottom of housing and drain lubricant.
2. Remove axle shafts.
3. Remove attaching stud nuts and break drive unit loose from axle housing with soft mallet and remove tapered dowels. Dowels must be removed before drive unit can be lifted from housing. Back out housing studs if necessary.

Fig. 1 Timken worm drive tandem axle units. Some units have the tapered bearing cage at the rear of both drive units. The tapered bearings shown are maintained by adjusting nuts. Units of more recent design have selective spacers to establish and maintain tapered bearing adjustment

DISASSEMBLE DRIVE UNIT

1. Remove flange nuts and stud nuts or capscrews from tapered cage cover. Hold forward yoke or flange of rear drive unit while loosening tapered bearing jam nut.
2. Pull yokes or flanges from worm shaft with suitable puller. Remove key (if used) from worm shaft.
3. Match mark one differential bearing cap and carrier leg to identify at reassembly.
4. Remove all locking wire and worm wheel baffle (if used). Remove differential bearing caps, bearing cups, adjusting nuts and differential assembly.

Disassemble Differential Unit

Two types of differential assemblies are used. One uses bolts and nuts to hold differential case halves to worm wheel; the other uses rivets.

1. To disassemble the bolt-on type, match mark differential case halves and worm wheel so parts can be correctly identified if they are to be re-used. Drive bolts from assembly with brass drift and pull assembly apart.
2. To disassemble the riveted-on type, match mark differential case halves and worm wheel for identification on reassembly if parts are to be re-used. Drill out rivets.

Tap differential case half free and remove side gear and thrust washer. Turn worm wheel over and repeat operation.

3. Match mark two halves of differential driving ring at matching lugs for reassembly. Some driving rings have a dowel and hole in respective halves to assure correct assembly.
4. Drive or press driving ring, spider, pinion and thrust washer assembly from worm wheel. Then separate halves of driving ring to disassemble spider and pinions.

Remove Worm Shaft

1. Remove worm shaft and tapered bearing cage from drive unit by tapping on end opposite tapered bearing cage.
2. Remove roller bearing or self-aligning bearing end of drive unit. Remove bearing cage or straight roller bearing cover and seal assembly. Remove roller bearing spacer (if used), roller bearing, and outer race lock screw, Fig. 2.
3. Carefully tap race from drive unit with brass drift. Remove roller bearing from cage and seal as required.
4. Remove worm shaft oil baffle (if used), Fig. 3. Identify location of one end of baffle to aid in reassembly.

Disassemble Worm Shaft & Tapered Bearing Cage

1. Remove attaching nut and related parts and press shaft out of bearing cage. Do not lose selective spacers that are between bearings.
2. Tap hardened steel spacer from roller bearing end of worm shaft.
3. Remove bearing cups from cage with suitable puller.
4. Remove seals or felts from front and rear covers or cages.

REASSEMBLY

Replace worm wheels that have worn or broken teeth and worm shafts where there is evidence of checked or damaged case hardening.

Inspect differential for pitted, scored or worn thrust surfaces of differential case halves, thrust washers, spider trunnions and differential gears. *Thrust washers must be replaced in sets. The use of a combination of old and new thrust washers will result in premature failure.* Check for wear or damage to differential gear teeth. Inspect spider trunnions for looseness in differential case or driving ring bores.

Worm & Tapered Bearing Cage

1. Press inner and outer tapered bearing cups in cage with suitable sleeve.
2. Position outer tapered bearing on suitable sleeve in press. Place cage and cup on outer bearing.
3. Position original selective spacers in cage on outer bearing, Fig. 4.

Fig. 2 Removing straight roller bearing outer race lock screw

Fig. 3 Removing oil baffle (when used)

Fig. 4 Installing selective bearing spacers

4. Press worm shaft into cage and bearing as cage is rotated to assure normal bearing contact. *Begin the assembly operation in the press making sure the parts are properly aligned. Press the parts together about ¼" to ⅜", then relieve the press pressure to permit them to realign themselves to prevent distortion or damage.* Continue the pressing operation until the parts are correctly assembled.
5. Install and tighten adjusting nut.

Tapered Bearing Preload

As shown in Fig. 5, wrap strong cord around tapered bearing cage three or four times and attach a pound scale to cord end. Pull scale on horizontal line and read pounds pull. Use rotating pounds pull (not starting pull). Tapered bearing preload may be measured while the assembly is in the press under pressure. The following table gives equivalent nut torques and press pressures:

Worm Shaft Thread Size	Specified Nut Torque Ft. Lbs.	Equivalent Press Pressure In Tons
1" x 20	300-400	6
1¼ x 18	700-900	11
1½" x 12	800-1100	14
1½" x 18	800-1100	14
1¾" x 12	800-1100	14
2" x 16	800-1100	14
2⅛" x 12	800-1100	14

Compute bearing preload torque by multiplying radius of bearing cage pilot by the number of pounds pull. For example, assume diameter of cage pilot is 6", the radius is 3". If the scale reading is one pound rotating pull, the bearing preload is 3 inch pounds. Tapered bearing preload should be zero worm shaft end play to 5 inch pounds maximum torque. If in excess of 5 inch pounds when nut is correctly tightened, remove nut and outer bearing cone and substitute a thicker spacer. If less than zero worm shaft end play, remove spacer and add one thinner than the one removed. Continue this procedure until correct bearing preload is obtained.

Adjust splined worm shaft tapered bearing preload in the same manner, omitting the seal and cover assembly (where used) until correct preload is obtained.

Position nut lock and washer (where used) over adjusting nut and tighten jam nut. Check tapered bearing preload and readjust if necessary. Carefully tap steel washer on opposite end of worm shaft.

Assemble Worm Shaft In Drive Unit

1. Coat oil seals with non-hardening sealing compound and assemble in cover or cage with suitable sleeve.
2. Install roller bearing outer race (where used) in drive unit with suitable sleeve. Be sure lock screw holes are properly aligned. Install and tighten bearing lock screw.
3. Note identifying location marks previously made on worm shaft oil baffle (new baffles have stenciled installation directions).
4. Install baffle so its tangs engage notches in drive unit. Position new gasket over tapered bearing cage studs.
5. Install worm shaft and bearing cage assembly in drive unit, Fig. 6.
6. Thread two or three strands of wire through oil baffle holes and twist wire to contract baffle, Fig. 7.
7. Tap worm shaft assembly into drive unit so baffle will fit against I.D. of tapered bearing cage. *Cut and remove wire, being sure no small bits of wire drop into drive unit.*
8. Install new gasket over tapered bearing cage flange and install cage cover or cover and seal assembly. Tighten stud nuts over lock washers.

9. Install roller bearing in opposite end of drive unit, or install self-aligning bearing and cage with new gasket. Install roller bearing outer washer and dowel assembly (if used).
10. Position new gasket over cover or cage and install assembly. Tighten stud nuts or capscrews.
11. When aluminum cover and seal assemblies are used, large flat steel washers are located beneath stud nut or capscrew lock washers.

Assemble Worm Wheel & Differential

Bolt-On Type

1. Assemble worm wheel to differential case half, carefully noting case matching marks. A suitable drift can be used in aligning case half and worm wheel holes.
2. Turn assembly over and install side gear thrust washer and side gear in case half.
3. Assemble differential pinions and thrust washers on spider. Install spider and pinion assembly in case half.
4. Install opposite side gear and thrust washer. Install opposite case half, carefully noting case matching marks.
5. Install two $\frac{7}{16}$" x 4½" bolts in assembly and tighten nuts. Check assembly for free rotation of gears.
6. *When a new worm wheel or differential case is installed, the case holes must be line-reamed with the worm wheel holes to properly reassemble, using correct size bolts. Use care to prevent ream chips from falling into assembly. Case holes may be covered with masking tape, Fig. 8, or plugged wth stoppers.*
7. Remove two bolts used to hold assembly together.
8. Install differential assembly bolts so heads are locked by case half flange shoulder and safety wire holes in bolts are roughly parallel to worm wheel O.D. Install and tighten nuts.

Fig. 5 Measuring worm shaft tapered bearing preload

Fig. 6 Installing worm shaft assembly

Fig. 7 Wire threaded through oil baffle holes to contract baffle

Fig. 8 Differential case holes covered with masking tape to prevent chips from falling into gear assembly when line-reaming case-to-worm wheel holes for bolt or rivet installation

The two case halves are usually identical except for width of bolt circle flange shoulder. Install bolts so that bolt heads will fit snugly against locking shoulder of one case half.

9. Lock bolts in groups of four with soft iron wire. Install differential bearings with suitable sleeve. Lubricate assembly.

Riveted Type

1. Assemble pinion and thrust washers on spider. Assemble spider assembly in half of differential driving ring.
2. Place assembly in worm wheel driving ring slots and assemble other half of driving ring, Fig. 9. Note previously made matching marks (or dowel and its hole) in matching driving ring lugs.
3. Support worm wheel on steel blocks and assemble driving ring and spider assembly to wheel by driving it in wheel slots with a soft hammer. Continue procedure until driving ring assembly is flush with machined face of worm wheel.
4. Install side gear and thrust washer. Assemble differential case half to worm wheel and driving ring assembly, noting differential case matching marks. A suitable drift can be used to aid in aligning case half-to-worm wheel holes.
5. Turn assembly over and install opposite side gear and thrust washer and case half. Note matching marks on case half.
6. Hold assembly together with two $\frac{7}{16}$" x 4½" bolts. Check for free rotation of gears.
7. *When a new worm wheel or differential case is installed, the case holes must be line-reamed with worm wheel holes to properly reassemble, using the correct size rivets. Use care to prevent rivet chips from falling into assembly. Case holes may be covered with masking tape, Fig. 8.*
8. Install rivets cold. When correct, rivet head being formed will be at least ⅛" larger in diameter than rivet hole. The formed head should not be more than $\frac{1}{16}$" lower than preformed head as excessive pressure may distort assembly and result in unsatisfactory tooth contact.
9. Install differential bearings with suitable sleeve. Lubricate assembly.

Fig. 9 Differential components used with riveted case

BOLTS AND STUD NUTS

Fig. 13 Torque specifications for Timken worm drive axles

Fig. 10 Satisfactory tooth contact. Starting at leaving side 30 to 60% full tooth length

Fig. 11 Not enough leaving side contact. Move worm wheel to leaving side

Fig. 12 Contact at entering side. Move worm wheel to entering side

Install Differential

1. Note identifying marks on bearing caps and install bearing cups, nuts and caps. Tighten nuts or capscrews. Then remove caps, cups and nuts. Lubricate parts and reassemble again, tightening nuts or capscrews securely.
2. Alternately loosen one adjusting nut and tighten the opposite nut while turning assembly to straighten bearing cups in bores and assure normal bearing contact.
3. Mount dial indicator to contact machined face of worm wheel and check end play. Establish a .000″ end play (no preload condition in bearings).
4. Tighten adjusting nuts 1¾ to 2½ notches tight (total for both nuts) to correctly preload bearings.

Worm Tooth Patterns

The worm wheel teeth have an entering side (where the worm shaft teeth enter) and a leaving side (where the worm shaft teeth leave). The entering sides of the teeth have the flattest angle while the leaving sides are almost straight or vertical.

The proper tooth contact during operation under load is approximately 80% of the tooth length, starting at the leaving side of the tooth, progressing toward the entering side of the tooth. *Do not have worm tooth patterns to have contact at the entering side.*

The correct tooth contact, when turned by hand before operation under load, should be 30 to 60% of worm wheel tooth length, starting at the leaving side of the tooth. To establish correct tooth contact, proceed as follows:

1. Apply a thin coating of Prussian blue to 6 or 8 worm wheel teeth.
2. Set the worm to its maximum amount of backlash, using a dial indicator.
3. Rotate worm shaft to wipe blue from worm wheel, indicating tooth contact.
4. Move worm wheel to one side or the other until contact, starting at the

leaving side is 30 to 60% of full tooth length, Fig. 10.

5. Always use drive side of teeth when making adjustments as coast side will automatically show a satisfactory pattern when drive side contact is correct. If tooth pattern shows as illustrated in Figs. 11 and 12, adjust as indicated. As a rule it is necessary to move the worm wheel only a few thousandths of an inch to alter tooth contact.
6. To adjust, move differential bearing adjusting nuts about ¼ turn at a time until proper tooth contact is obtained. Maintain differential bearing preload during adjustment by first loosening the adjusting nut on the side toward which the differential is to be moved and tightening the opposite adjusting nut the same amount. *Make normal wear adjustments at the left hand bearing only. This will maintain correct worm and wheel alignment.*

Final Assembly

1. Tighten differential bearing cap nuts or capscrews. Install nut locks and lock screws and secure with lock wire.
2. Install and tighten yoke and flange nuts.
3. With new gasket, install drive unit in housing. First install lock washer and stud nuts under any drive unit and housing offset. It is impossible to start these nuts after drive unit is tight in housing.
4. Install tapered dowels (where used). Alternately tighten nuts.
5. Connect U-joints at worm shaft. Install axle shafts and connect brake lines.

Split Housing Axle

The Timken split Housing Type, Fig. 1, is a single reduction, hypoid geared axle. The differential and gear assembly is mounted on tapered roller bearings with the cups assembled in the case and cover halves of the unit. The straddle-mounted pinion has two tapered roller bearings and a radial thrust bearing. The tapered roller bearings are located forward of the pinion teeth and the radial bearing at the inner end of the pinion.

Fig. 1 Timken Unit Housing Type Axle

Removing Axle

1. Remove plug from bottom of axle housing and drain lubricant.
2. Disconnect universal at pinion shaft.
3. Disconnect brakes.
4. Remove spring clips.
5. Remove axle from under vehicle.
6. Remove axle shaft stud nuts and washers.
7. Rap axle shafts sharply in center of flange with a heavy steel hammer to free dowels. Remove taper dowels and axle shafts, and carefully remove outer oil seal assemblies.
8. Remove wheels.
9. Place axle assembly in vise, holding by the tube on the case half.

Disassemble Axle

1. Before proceeding, place length of pipe or suitable support slightly smaller than the axle shaft splines approximately two-thirds through the axle from the case side to prevent dropping the differential assembly.
2. Remove bolts, nuts and washers from case and cover and remove cover half.
3. Remove differential and gear assembly.
4. Remove support pipe.

Disassemble Differential & Gear

1. If original identification marks are not clear, mark differential case halves with a punch before disassembling for correct alignment when reassembling.
2. Cut lock wire, remove bolts and separate case halves.
3. Remove spider, pinions, side gears and thrust washers.
4. Remove rivets and separate gear and case if required. In removing rivets, carefully center punch rivets in center of head. Use drill $\frac{1}{32}''$ smaller than rivet body to drill through head. Press out rivets.
5. Use bearing puller to remove bearings if necessary.

Remove Pinion & Cage

1. Secure yoke with holding tool and remove pinion shaft nut and washer.
2. Insert puller through yoke and remove.
3. Remove pinion bearing cover and oil seal assembly.
4. Remove pinion and cage assembly, using puller screws in holes provided. Driving pinion from inner end with a drift will damage the bearing lock ring groove.

Disassemble Pinion & Cage

1. Tap shaft from cage with soft mallet or press shaft from cage.
2. Remove outer bearing from cage.
3. Remove spacer or spacer combination from pinion shaft.
4. Remove rear thrust bearing and radial bearing with bearing puller if necessary to replace.
5. Remove oil seal from bearing cover.
6. If necessary to remove differential bearing cups, wire the selective spacers which are behind the cups to their respective axle halves.

Differential Pinion Bushings

If necessary to replace these bushings, proceed as follows:

1. Split the worn bushing with a hacksaw and drive it out.
2. Remove burrs or sharp corners from inner edge of pinion bore to prevent shearing or buckling of bushing on installation.
3. Place pinion on anvil. Position bushing in inner end of pinion bore and press squarely into position. Use adapter with correct size offset to fit bushing.
4. Use bar to press burnishing ball through bushing. If desirable, the bar may be shortened to permit the use of a bench vise to install and burnish bushing.

Reassemble Pinion & Cage

When a new pinion is required, the bearing and cage assembly furnished for service purposes should be used. This

Fig. 2 Checking pinion shaft bearing preload

Fig. 3 Layout of differential parts

Fig. 4 Align mating marks before assembling differential case halves

includes the cage with bearing cups assembled, bearing cones and selective spacer required to obtain the correct bearing preload. The used bearing cones should be removed from the pinion shaft and the new bearings and spacer used in the assembly.

1. Press rear thrust and radial bearings firmly and squarely against the pinion shoulders with a suitable sleeve.
2. Install radial bearing lock ring and squeeze ring into pinion shaft groove with pliers.
3. If new cups are to be installed, press firmly against pinion bearing cage shoulders.
4. Lubricate bearings and cups with light machine oil.
5. Insert pinion and bearing assembly in pinion cage and position spacer or spacer combination over pinion shaft.
6. While in a press under 25,000 pounds pressure, check bearing preload torque. Wrap soft wire around cage, Fig. 2, and pull on a horizontal line with a pound scale. If a press is not available, the yoke may be installed and the pinion nut tightened to 300-400 foot pounds torque for checking. If rotating torque is not within 12-18 inch-pounds, use thinner spacer to increase or thicker spacer to decrease preload. As an example, assuming the pinion cage diameter to be 6″, the radius would be 3″ and with five pounds pull would equal 15 inch-pounds preload torque.
7. Press yoke against forward bearing and install washer and pinion shaft nut.
8. Place pinion and cage over carrier studs. Hold yoke and tighten pinion shaft nut to 300-400 foot-pounds torque.
9. Recheck pinion bearing preload torque. If rotating torque is not within 12-18 inch-pounds, repeat foregoing procedure.
10. Hold yoke and remove pinion shaft nut and yoke.
11. Lubricate pinion shaft oil seal and cover outer edge of seal body with a non-hardening sealing compound. Press seal against cover shoulder with seal driver.
12. Install new gasket and bearing cover.
13. Press yoke against forward bearing and install washer and pinion shaft nut.
14. Tighten pinion shaft nut to 300-400 foot-pounds torque and install cotter key. Do not back off nut to align cotter key holes.

Assemble Differential & Gear

1. Rivet bevel gear to case half with new rivets. If a new gear or differential case is to be used, the rivet holes in the gear and case should be checked for alignment and line-reamed if necessary. The gear must be tight on the case pilot and riveted flush with the differential case flange. Check with a .002″ feeler gauge. Rivets should not be heated but should be upset cold. When the correct rivet and rivet set is used, the head being formed will be at least ⅛″ larger in diameter than the rivet hole. The head will then be approximately the same height as the preformed head. The formed head should not exceed $\frac{1}{16}$″ less than the preformed head as excessive pressure will cause distortion of the case holes and result in gear eccentricity.
2. Lubricate differential case inner

Fig. 5 Installing differential bearing spacer

Fig. 6 Installing differential and gear into case

Fig. 7 Checking differential and gear end play with dial indicator through thrust block pin hole

Fig. 8 Checking gear lash with dial indicator

walls and all component parts, Fig. 3, with axle lubricant.
3. Position thrust washer and side gear in bevel gear and case half.
4. Place spider with pinions and thrust washers in position.
5. Install component side gear and thrust washer.
6. Align mating marks, Fig. 4, position component case half and draw assembly together with four bolts equally spaced.
7. Check assembly for free rotation of differential gears and correct if necessary.
8. Install remaining bolts, tighten to 80-110 foot-pounds torque and thread with lock wire.
9. If bearings are to be replaced, press them firmly and squarely on differential case halves.

Adjust Differential Bearing Preload

1. Remove thrust block, using drift to drive pin out of cover.
2. Install differential bearing spacers, Fig. 5, in the original position if new bearing cups are installed. Spacers must be installed with the chamfered edge toward the machined surfaces in the housing.
3. Insert pipe used for disassembling case half.
4. Position differential and gear over pipe, Fig. 6, with gear facing the case half and slide into position.
5. Install new gasket over case flange.
6. Position cover half over pipe and draw axle halves together with six bolts equally spaced.
7. Check differential and gear assembly end play with dial indicator through thrust block pin hole against gear, Fig. 7. Both differential bearing preload and gear lash are controlled by selective spacers, available in thickness steps of .003", which are installed between the differential bearing cups and the case and cover halves of the axle housing. Bearing preload may be increased or decreased by using a thicker or thinner spacer respectively in the cover half of the assembly. The gear may be moved toward the pinion, decreasing the gear lash, by decreasing the thicknes of the spacer in the case half and increasing the thickness of the spacer by the same amount in the cover half. Reversing this transposition will move the gear away from the pinion and increase the gear lash. The correct preload of .008" to .013" tight is obtained as follows:
8. Increase or decrease the thickness of the spacer used in the cover half to obtain a freely rotating gear with from .000" to .005" end play.
9. Remove spacer in cover half and install a spacer .008" plus the end play thicker than the spacer used to obtain .008" to .013" preload.
10. If a new gear or case has been installed, check runout at back face of gear. Correct and recheck if runout exceeds .005".
11. When adjustment is satisfactory, remove cover and move differential and gear out on support sufficient to permit installation of pinion and cage assembly.
12. Install thrust block and pin.

Install Pinion & Cage

1. Coat cage flange contact surface with non-hardening sealing compound and position cage assembly over studs and tap into position with a soft mallet.
2. Install lock washers and stud nuts and tighten to 70-90 foot-pounds torque.

Check & Adjust Gear Lash

1. Install differential and gear assembly and assemble cover with six bolts equally spaced and tighten to 85-95 foot-pounds torque.
2. Check gear lash with dial indicator from a position 2" from pinion shaft center, Fig. 8. The amount indicated at this point will be twice the amount of the actual gear lash.
3. Transpose spacers used in both case and cover, decreasing the thickness of the spacer on the side in the direction which the gear is to be moved and increasing the thickness of the opposite spacer exactly the amount as required to obtain the correct gear lash of .006-.012" (.012-.024" on indicator).
4. Install remaining bolts, washers and nuts in housing and tighten all nuts in bolt circle to 85-95 foot-pounds torque.

Install Axle in Vehicle

1. Position axle under vehicle and install spring clips.
2. Clean and lubricate hub cavity and wheel bearings if required.
3. Install wheels and adjust wheel bearings.
4. Install new outer oil seal if required.
5. Install axle shafts, using new gaskets. Tighten stud nuts to 85-95 foot-pounds torque.
6. Connect brakes and universal joint.

Electric Shift Unit For Two-Speed Axles

DESCRIPTION

Basically, the shift unit, Fig. 1, consists of an electric motor, a worm shaft and wheel, an eccentric and a connecting rod. The electric motor drives the worm shaft and wheel; the eccentric is attached to the worm wheel and drives the connecting rod which operates the shift shaft.

The actual shifting is done by a double acting compressing spring contained in the push rod. This spring is mounted on the shift shaft which is attached to the connecting rod. As the connecting rod pushes (or pulls) the shift shaft, the spring cocks and, in turn, pushes or pulls on the push rod and shift collar. When the driving torque is relieved (by releasing the accelerator or clutch) the spring pressure will complete the shift.

SIDE MOUNTED TYPE

Removal

1. Disconnect electric harness at terminals at shift unit cover.
2. Remove attaching screws and filler plug from cover.
3. Screw a threaded tool into the filler plug hole and pull the cover from the housing. The tool is made from a 1/8 x 27 pipe plug welded to the end of a T handle. *Do not pry cover from housing.*
4. Drive roll pin from shift shaft, using tool having a 5/8" body and a $\frac{5}{32}$" nose section. *If the roll pin is in line with the worm shaft, it will be necessary to change the position of the shift shaft before the pin can be driven out.*
5. To change the position of the shift shaft, turn on the vehicle ignition switch. Shift the unit to the desired position by touching the hot lead of the wiring harness to the left-hand terminal on the shift unit cover. It is not necessary to attach the cover to the housing. *If the shift motor is not operating, disconnect the wires at the inner face of the cover and remove the motor as outlined under Disassembly. Then install a new motor and shift the unit to the desired position. In case a new motor is not available, use a slotted tool that fits over the tang of the worm shaft and turn it until the shift shaft changes position.*
6. Unfasten and remove shift unit. Do not damage oil seal located in flange section.

Disassembly

1. Disconnect wires from terminals on inside face of cover.
2. Remove two stud nuts and star washers that hold motor to housing.
3. Carefully break loose motor and remove it and gasket from housing.
4. Loosen jam nut and remove adjusting screw. *Do not lose ball bearing that rides in recess of adjusting screw.*
5. Remove worm shaft assembly and disassemble it if necessary. *The spring retainer at bottom of worm shaft is pressed on and cannot be removed by hand. However, it can be removed by holding it in a vise and driving the shaft out.*

Fig. 1 Electric shift for two speed axles

6. Remove worm wheel and eccentric assembly. To disassemble, hold assembly in vise and remove three capscrews and lockwashers. Drive eccentric shaft out of assembly.

Reassembly

1. Reassemble worm shaft and position it in shift housing.
2. Install shift motor with gasket to housing. Slot in motor shaft fits over tang of worm shaft.
3. Install and tighten two locking stud nuts that secure motor.
4. Place ball bearing in recess of adjusting screw.
5. Turn adjusting screw in until the ball bearing is snug against bottom of worm shaft. Then back off screw 1/8 turn for proper adjustment. Hold adjusting screw in place and tighten lock nut. Check to see that worm shaft turns freely by hand.
6. Reassemble worm wheel and eccentric. *The eccentric shaft should protrude an equal distance at top and bottom of the assembly.* Install assembly in position shown in Fig. 2.
7. Connect electric leads on inside face of shift cover. Attach red wire to terminal closest to flange of shift unit.

Installation

1. Position shift fork in cross shaft shift collar groove.
2. Slide push rod into shift fork. Line up set screw hole in fork with recess in push rod.
3. Install shift fork set screw and tighten jam nut to 30 - 33 lb. ft. torque. Be sure set screw enters recess in push rod.
4. Lock set screw to fork with wire.
5. Remove screws from shift unit cover.
6. Remove cover from housing, using a tool made from a 1/8 x 27 pipe plug welded to the end of a T handle and screwed into filler plug hole. Do not pry cover.
7. Move shift unit to neutral position as shown in Fig. 3.
8. Move cross shaft shift collar to neutral (central) position.
9. Install new shift housing to sleeve gasket.
10. Position shift unit over mounting studs. Do not damage oil seal installed in flange section of shift housing.
11. Move connecting rod into slot in end of shift shaft.
12. Install lockwashers and mounting stud nuts. Tighten nuts to 26 - 29 lb. ft. torque.
13. Line up hole in connecting rod with hole in end of shift shaft.
14. When holes are lined up, drive roll pin into place with a suitable driver.
15. Install gasket and cover. *To install cover, shift unit and axle assembly must be in neutral position to avoid damaging the switches.*
16. Fill unit to bottom of filler hole with SAE 10 motor oil. Install filler plug.

Connect Electric System

If a vacuum or air shift unit is being replaced by the electric type, it will be necessary to install an electric hook-up from the cab of the vehicle to the electric shift unit.

If the spur pinions on the cross shaft are located in the conventional manner, with the HI speed (larger) pinion next to the drive gear, Fig. 4, connect the red wire to the terminal indicated in Fig. 5, with the black wire connected to the other terminal.

If the spur pinions are located in the wide range manner, with the LO (smaller) pinion next to the drive gear, Fig. 6, connect the red wire to the terminal indicated in Fig. 5, with the black wire connected to the other terminal.

Fig. 2 Worm wheel and eccentric installed

Fig. 3 Shift unit in neutral position

Fig. 4 Location of gears on cross shaft with conventional ratio

Fig. 5 Electric shift wiring hook-up

Check Operation of Shift Unit

1. Turn on ignition switch.
2. Flip switch button in cab to operate shift unit. One man can operate switch while another observes movement of shift collar on cross shaft through pinion cage bore.
3. Check to make sure shift collar completes shift into both HI range and LO range. The engaging teeth on shift collar must completely engage corresponding teeth of spur pinions. Incomplete shifts can cause serious axle failures.

Adjustments

1. Shift collar travel can be equalized by altering the shim pack installed behind flange of push rod sleeve.
2. Check clearance of shift fork pads in shift collar with feeler gauge, Fig. 7. Clearance should not be less than .010″ on each side of fork in both HI and LO speed positions. *When checking shift fork clearance, shift collar must be flush with end face of engaged spur pinion.*
3. Add or remove shims from pack under sleeve to obtain correct adjustment.

Final Assembly

1. If above adjustments are satisfactory, install shims, pinion and cage assembly, and capscrews.
2. Connect universal joint at pinion shaft.
3. Load vehicle and test operation of shift unit under actual operating conditions.

FRONT MOUNTED TYPE

Removal

1. Disconnect wires from terminals on shift cover.
2. Unfasten and remove shift unit from carrier. *The push rod must be drawn in toward shift housing before it can be removed from carrier, otherwise it will not clear bore in carrier.*
3. To move push rod to correct position, first turn on ignition switch. Then shift the unit by touching the hot lead of the wiring harness to the right-hand terminal. If shift motor is not working, see procedure under *Change Position of Shift Shaft* in the Side Mounted Type procedure. Do not attempt to force or pry shift unit from carrier.

Disassembly

1. Remove cover attaching screws and filler plug.
2. Screw a threaded tool into filler plug hole and pull off cover. Tool can be made from a 1/8 x 27 pipe plug welded to the end of a T handle. Do not pry off cover.
3. Drive roll pin from shift shaft. *If roll pin is in line with worm shaft, it will be necessary to change position of shift shaft by turning the worm.*

Fig. 6 Location of gears on cross shaft with wide range ratio

Fig. 7 Checking clearance of shift fork pads in shift collar with feeler gauge

Fig. 8 Positioning push rod to permit entry in carrier bore

Fig. 9 Shift collar travel adjustment. Front mounted type

4. Remove two stud nuts and separate shift unit from push rod and bracket assembly.
5. Proceed with disassembly as outlined for the Side Mounted Type.

Reassembly

1. Install worm shaft assembly, shift motor, adjusting screw, and worm wheel and eccentric assembly as outlined for the Side Mounted Type.

2. Place worm shaft and worm wheel in the neutral position (see Fig. 3).
3. Install push rod and bracket assembly. Tighten nuts to 26 - 29 lbs. ft. torque.
4. Slide connecting rod into slot at end of shift shaft.
5. Line up hole in connecting rod with hole in shift shaft and install roll pin with suitable driver.
6. Connect wire leads at inside face of shift cover. Attach red wire closest to flange of shift unit.
7. Install cover with new gasket. The shift unit must be in neutral position when cover is installed to avoid damage to switches.

Installation

1. Move cross shaft shift collar to engage spur pinion opposite drive gear.
2. Shift the unit to the corresponding position (with push rod drawn in toward shift unit housing, Fig. 8). Push rod must be in "right" position, otherwise it will not fit in carrier bore. *To shift the unit, use a battery and two leads; ground one lead and touch the other to the right-hand terminal on the cover.*
3. Install new gasket and slide shift unit into carrier bore.
4. Remove inspection cover from top of carrier and look inside to guide push rod bellcrank into slot in shift shaft.
5. Install and tighten attaching capscrews to 26 - 29 lb. ft. torque.
6. Fill unit with SAE 10 motor oil to filler plug hole. Install filler plug.

Connect Electric System & Check Operation

Connect wires as outlined for the Side Mounted Type. Check the operation of the shift unit as outlined for the Side Mounted Type, observing the movement of the shift collar through the inspection hole at top of carrier.

Adjustments

Shift collar travel can be adjusted by the stop screws installed in the carrier assembly, Fig. 9. One stop screw is installed in cross shaft bearing cage, opposite the drive gear, and the other is installed in the top of the carrier. *Do not disturb settings of stop screws unless shift fork adjustments are required.*

1. If necessary to adjust, first be sure fork and collar are shifted to engage the helical pinion next to the drive gear. Then adjust the stop screw and lock nut in the top of the carrier so that the fork is centered in the collar groove within .005".
2. With fork and collar shifted to engage pinion away from drive gear, adjust stop screw and lock nut in the cross shaft bearing cage so that the fork is centered in the collar groove with .005".
3. When checking shift fork clearance in collar groove, collar must be flush with end face of spur pinion in both the HI and LO speed positions.

TIMKEN (Rockwell-Standard) TRANSFER CASES

See Willys Chapter For It's Transfer Case

INDEX & LUBE CAPACITY

The capacities of these transfer cases are given in vertical (transverse and horizontal) fore and aft position. Transfer cases may be mounted at various angles by the vehicle manufacturer and normally should be filled to the top of the filler neck or bottom of the tapped hole. Capacities will vary depending upon the angle of mounting.

Fig. 1 Typical hook-up of a three shaft transfer case on a 6 x 6 vehicle

Fig. 2 Typical hook-up of a four shaft transfer case on a 4 x 4 vehicle

DESCRIPTION

A transfer case is a gear box located between the main transmission and the rear axle. Its purpose is to transfer power from the transmission to the front driving axle as well as the rear driving axle. It also provides an extra gear reduction (LO) in the power train of the vehicle.

Most units are available with a Power Take Off and a parking brake. Every unit incorporates a Front Axle Declutch which is used to drive the front axle whenever the vehicle encounters steep grades or rough terrain. These accessories are actuated by separate shift levers located in the cab of the vehicle.

Fig. 1 shows a typical hook-up of a three-shaft transfer case, while Figs. 2 and 3 illustrate a typical hook-up of a four-shaft transfer case used with a 4 x 4 and a 6 x 6 vehicle, respectively.

Fig. 3 Typical hook-up of a four shaft transfer case on a 6 x 6 vehicle

Three Shaft Transfer Case

DISASSEMBLY

1. Referring to Figs. 4 and 5, remove drain plug and drain lubricant.
2. Remove power take-off unit and wire shims together for reassembly.
3. Remove front axle declutch unit.
4. Remove input and output shaft yokes or companion flanges.
5. Remove range shift shaft and fork.
6. Remove shift cover. Cover is spring-loaded and should be held down during removal to prevent injury. Take out detent ball, plunger and spring.
7. Loosen shift fork nut and screw shift shaft out of fork and slide it out of case.
8. Loosen set screw in mainshaft driving clutch and remove clutch and oil dam.
9. Drive tapered pins from cover and remove cover.
10. Lift mainshaft assembly from case.
11. Lift out axle drive shaft assembly and then remove idler assembly.

Disassemble Power Take-Off

1. Remove yoke from power take-off shaft.
2. Remove oil filler plug from cage. Then remove detent capscrew, spring and ball.
3. Remove oil seal cage, shims and gasket.
4. Through oil filler plug hole, loosen shift fork set screw. Disconnect shift lever and pull shift shaft from housing.
5. Use a bronze drift and drive power take-off shaft from housing. Remove shift fork and sliding clutch. *Do not disassemble further unless bearings need replacing.*

Disassemble Front Axle Declutch Unit

1. With suitable puller, remove declutch shaft yoke.

Fig. 4 Timken three shaft transfer case

2. Remove bearing cage from housing.
3. Remove detent parts from housing.
4. Unscrew filler plug and loosen shift fork set screw.
5. Slide shift shaft out of housing. If necessary, remove shift and shaft oil seal.
6. Remove sliding clutch and shift fork.
7. If necessary, press apart bearing cage assembly. Remove outer bearing cup and oil seal.

Disassemble Shaft Assemblies

1. To disassemble mainshaft, press off front bearing and remove sliding gear. Press drive gear, bearing spacer and rear tapered bearing from shaft. Remove ball bearings and spacer from drive gear.
2. To disassemble axle drive shaft, remove set screw and pull off driving clutch. Press rear bearing and gear from shaft. Press off front bearing. Remove pilot bushing from shaft with a suitable puller if necessary.
3. To disassemble idler shaft, remove snap ring at low gear end. Slide off speedometer drive gear and remove Woodruff key. Remove front bear-

Fig. 5 Disassembled view of a Timken three shaft transfer case

ing snap ring. Press off low gear and remove spacer. Invert assembly and remove bearing retainer. Press off high gear and bearing.

Disassemble Case & Cover

1. Remove mainshaft front seal cage and idler shaft front bearing cap from transfer case housing.
2. Remove idler shaft bearing cover.
3. Pull axle drive shaft rear bearing cage, using puller screws. Wire shims together for reassembly. If necessary, press mainshaft rear bearing cup from cover.

REASSEMBLY

Assemble Axle Drive Shaft

1. Referring to Fig. 6, press pilot bushing into bore at front of shaft.
2. Press front bearing into place.
3. Press driven gear and rear bearing into place, using a suitable sleeve that bears against inner race.
4. Slide driving clutch onto shaft and install set screw. Screw must enter recess in shaft.

Assemble Idle Shaft

1. Referring to Fig. 7, press low gear and tapered bearing into place on shaft. *Use a sleeve that will clear bearing journal.*
2. Install bearing snap ring, and Woodruff key in keyway.
3. Place speedometer drive gear on shaft and install outer snap ring.
4. Invert assembly and install spacer and high gear. Place bearing on shaft and press into position. Install bearing retainer, capscrews and lock wire.

Assemble Mainshaft

1. Referring to Fig. 8, tap rear ball bearing into gear with suitable sleeve against outer race.
2. Position bearing spacer in gear and tap front ball bearing into gear.
3. Press gear assembly onto shaft until it seats against shoulder on shaft.
4. Position spacer and press rear tapered bearing onto shaft.
5. Install sliding gear and front bearing. *Do not install oil dam and power take-off driving clutch until after transfer case cover has been attached.*

Fig. 6 Axle drive shaft components. Three shaft case

Fig. 7 Idler shaft components. Three shaft case

Fig. 8 Mainshaft components. 8hree shaft case

Fig. 10 Checking end play of axle drive shaft

Fig. 9 Front axle declutch unit. Three shaft case

Fig. 12 Checking end play of power take-off unit

Fig. 11 Power take-off components. Three shaft case

Assemble Front Axle Declutch Unit

1. Referring to Fig. 9, hold shift fork in place inside declutch housing and install sliding clutch. Position fork in groove.
2. Slide shift shaft through housing bore and into shift fork. Install and tighten set screw. Install oil filler plug.
3. Install detent ball, spring, lockwasher and lock screw in housing. Tighten lock screw.
4. Install inner and outer bearing cups in declutch bearing cage.
5. Press inner bearing on shaft with suitable sleeve.
6. Position bearing spacer on shaft and then install bearing cage.
7. Press outer bearing onto shaft. *Do not install oil seal at this time.*
8. Mount cage in vise and install yoke or flange and tighten nut to specified torque.
9. Check bearing adjustment by using a dial indicator at the end of the shaft as shown in Fig. 10. *Since the specified bearing adjustment is zero end play and zero preload, there should be no reading on the dial gauge.*
10. If there is no end play in the assembly, turn the shaft by hand to check for bearing preload. There should be no more than a slight drag on the shaft.
11. If there is end play in the assembly, use a thinner spacer between the bearings; if there is preload, use a thicker spacer.
12. Once the proper adjustment is obtained, remove the yoke or flange and install oil seal in bearing cage.
13. Position a new gasket over studs at front of declutch housing.
14. Line up front axle shaft with sliding clutch and slide shaft and bearing cage into housing.
15. Install lockwashers and stud nuts, tightening nuts to specified torque. Install yoke or flange and tighten nut to specified torque.

Assemble Power Take-Off

1. Referring to Fig. 11, press inner bearing cup into P.T.O. housing with a suitable sleeve.
2. Hold shift fork and sliding clutch in place inside housing.
3. Slide shaft assembly (with inner and outer bearings) into housing. Check to see that shift fork is seated in sliding clutch groove.
4. Install outer tapered bearing cup with a suitable sleeve.
5. Slide clutch shaft into housing and through shift fork.
6. Line up recess in shift shaft and install shift fork set screw and tighten.
7. Install detent ball, spring, lockwashers and capscrew. Tighten capscrew.
8. Attach shift lever to shift shaft.
9. Position new gasket and install enough bearing adjustment shims to set up end play in the assembly.

Fig. 13 Pump type P.T.O. Pump is actuated by an eccentric located on the P.T.O. shaft to assure proper lubrication during "stationary" operation of the P.T.O.

Fig. 14 Torque specifications for three shaft transfer case. Torques given are for parts coated with machine oil. For dry (or "as received") parts, increase torque 10%. For parts coated with multi-purpose gear oil, decrease torque 10%. Nuts on studs use same torque as for driving the stud

10. Attach seal cage to housing and tighten capscrews.
11. Using a dial indicator at end of shaft, Fig. 12, check amount of end play in the assembly. End play should be .003-005".
12. Take off seal cage and remove enough shims to establish proper end play. For example, if dial reading is .009", remove .005" of shims to arrive at an adjustment of .004".
13. Reinstall seal cage and tighten capscrews to specified torque. Install yoke or flange and tighten nut to specified torque. See Fig. 13 for optional pump type power take-off.

Installation of Shafts

1. Position axle drive shaft in case.
2. Tilt axle drive shaft to one side and install idler shaft. Then work both assembles into position.
3. Position mainshaft in case and work into position.
4. Reassemble transfer case cover (if disassembled). Use original shim packs under idler shaft and axle drive shaft rear bearing caps.
5. Install transfer case cover but do not tighten nuts at this time. Install dowels; then tighten nuts to specified torque.
6. Install front axle declutch unit with new gasket. Tighten stud nuts to specified torque.
7. Position oil dam and P.T.O. driving clutch on mainshaft and install set screw.
8. Install new gasket and shim pack. Then mount P.T.O. assembly on cover. Tighten stud nuts to specified torque.

Checking Bearing Clearances

1. Mount a dial indicator at forward end of mainshaft and measure end play in assembly. Specified bearing adjustment is .003-.005" end play. To adjust, alter shim pack located between P.T.O. and transfer case cover.
2. In a similar manner, measure axle drive shaft end play with a dial indicator at rear end of shaft. End play is also .003-.005 and is adjusted by altering shims.
3. Idler shaft end play can be checked by inserting a pry bar through shift cover hole at top of case and working idler shaft low gear back and forth. No more than a very slight bit of end play should be felt.

Final Assembly

1. Position shift fork in transfer case so that it fits in groove of mainshaft sliding gear.
2. Slide shift shaft into case and screw it into shift fork.
3. Tighten bolt in shift fork and secure with lockwashers and nut.
4. Install detent ball in transfer case Position plunger in detent spring and install in case.
5. Place shift fork cover gasket, breather plate and cover on case. Press cover down to compress detent plunger spring. Hold down cover and install lockwashers and capscrews.
6. Install yoke or flange on mainshaft and tighten nut to specified torque.
7. Install companion flange at rear of axle drive shaft. Tighten nut to specified torque.

Lubrication

Install and tighten drain plug. Turn transfer case upright and pour ½ pint of recommended lubricant through filler plug opening. Add some oil to P.T.O. and front axle declutch unit. Do not fill unit to specified level until it is installed in the vehicle. Test operation of transfer case in all ranges.

Four Shaft Transfer Case

Fig. 15 Timken "clover leaf" four shaft transfer case

DISASSEMBLE

1. Referring to Fig. 15, remove all yokes or flanges.
2. Remove P.T.O. assembly or rear cover if P.T.O. is not used.
3. Remove transfer case cover.
4. Remove detent balls and springs.
5. Pull both shift shafts out through front of case if possible. Otherwise, use a soft metal drift and drive shafts and expansion plugs out through rear of case.
6. Remove oil seals from front of case if necessary.
7. Lift out range and declutch forks.
8. Pull front output shaft and declutch collar from case.
9. Slide a bar through front output shaft gear and tap out small and large expansion plugs located in brake section.
10. Remove brake drum, brake hub retaining ring and hub with a suitable puller. Remove brake shoes and lever, and brake backing plate.
11. Remove idler shaft front and rear bearing caps. Wire forward cap shims together for reassembly.
12. Remove bearing retainer plate from front end of idler shaft and press shaft out through rear of case. Lift out low gear, spacer and front bearing.
13. Remove high gear. Tap front bearing cup from case. Remove snap ring and press rear bearing from idler shaft.
14. Remove front output gear rear bearing cap and gasket.
15. Take off bearing snap ring and tap front output gear into case. Reach through cover opening and lift out gear and bearing. Press off radial bearing.
16. Take off rear output shaft front and rear bearing caps. Wire shims together for reassembly.
17. Remove input shaft front bearing cover. Wire shim pack together for reassembly.
18. Using a block of wood between sliding gear and case, press out input shaft and front bearing. Do not pound on shaft if gear becomes bound. Lift out sliding gear, drive gear and spacer. Remove front bearing from shaft.

REASSEMBLY

Assemble P.T.O. Unit

1. If this unit was disassembled, refer to Fig. 16 and proceed as follows:
2. Install ball bearings on P.T.O. shaft.
3. Position wiper against inner bearing. Install snap ring in groove of outer bearing.
4. Slide shaft into housing and install sliding clutch on inner end.
5. Position new gasket and install oil seal cage.
6. Place shift fork in groove of sliding clutch. Slide shift shaft into bore of fork.
7. Line up recess in shaft with set screw and tighten screw. Lock wire set screw to fork.
8. Install expansion plug in shift shaft hole.
9. If necessary, replace shift shaft oil seal in front of housing.

Assemble Input Shaft

1. Referring to Fig. 17, install front bearing on shaft with shielded side against shoulder.
2. Start shaft into case. Mount sliding gear, spacer and drive gear (with bushing) on shaft.
3. Tap shaft into position using a suitable sleeve against inner race of front bearing.
4. Position original shim pack plus .010" more to make sure there is end play in the assembly. Install front cover and tighten capscrews.
5. Place thrust washer on shaft and install rear bearing with shielded side toward inside.
6. Position new gasket and attach the P.T.O. or cover to rear side of case.

Fig. 16 Power take-off for four shaft transfer case

Fig. 17 Input shaft components. Four shaft case

Fig. 18 Rear output shaft components. Four shaft case

Fig. 19 Idler gear components. Four shaft case

7. Mount a dial indicator on the unit. Set the stem against the front end of the input shaft and check the amount of end play in the assembly. Remove enough shims from under the bearing cap to arrive at an adjustment of .003-.005″ end play.
8. Reposition bearing cap, insert capscrews and torque to specifications. Remove P.T.O. for convenience in handling transfer case.

Install Rear Output Shaft

1. Referring to Fig. 18, press front bearing onto shaft with suitable sleeve.
2. Hold rear output gear in position inside case and slide shaft through it.
3. Install front bearing cup and original shim pack plus .010″. Install bearing cover with lockwashers and tighten capscrews.
4. Press rear bearing on shaft with a suitable sleeve. Then tap bearing cup into position.
5. Install spacer and speedometer drive gear over shaft.
6. Position new gasket, bearing cap and oil seal over shaft. Install lockwashers and capscrews and tighten to specified torque.
7. Rotate shaft to seat bearings. Mount a dial indicator against rear end of shaft to check the amount of end play in the assembly. Remove enough shims from under the front bearing cap to obtain an adjustment of zero end play and zero preload.

Install Front Output Gear

The front output gear must be installed in the case before the idler assembly is installed.

1. Install ball bearing on hub of gear.
2. Position gear and bearing in case and install snap ring on bearing.
3. Install rear bearing cap over new gasket. Insert capscrews and lockwashers and tighten to specified torque.

Install Idler Gear

1. Referring to Fig. 19, press rear bearing on idler shaft. Install snap ring.
2. Hold high gear in position inside case and tap idler shaft through it with a soft hammer. Short hub side of gear goes to the outside (rear).
3. Install rear spacer on shaft and then install low gear with long hub toward outside (front) of case.
4. With shaft in position, install rear bearing cup in case. Use a new gasket and install rear bearing cap, lockwashers and capscrews. Tighten to specified torque.
5. Drive front bearing onto idler shaft. Hold shaft rigid to avoid damaging rear bearing and cup. Install bearing retainer plate. Lock wire capscrews.
6. Tap front bearing cup into place.
7. Install enough shims to set up end play in the idler assembly. Install front bearing cap and secure with lockwashers and capscrews.
8. Mount a dial indicator on the case with the stem set against the inside face of the low gear. Check the

Fig. 20 Front output shaft components. Four-shaft case

Fig. 21 Torque specifications for four shaft transfer case. Torques given apply to parts coated with machine oil. For dry (or "as received") parts, increase torque 10%. For parts coated with multi-purpose gear oil, decrease torque 10%. Nuts on studs use same torque as for driving the stud

amount of end play by working the assembly back and forth with two pry bars. Remove enough shims to obtain .003-.005" end play.

Install Front Output Shaft

1. Referring to Fig. 20, install bearing on shaft with bearing snap ring toward outside.
2. Install sliding collar on shaft and slide shaft into case.
3. With shaft in position, install new gasket, bearing cap and oil seal, lockwashers and capscrews. Tighten to specified torque.

Install Parking Brake

1. Position new gasket and mount backing plate, deflector and stamped washer. Insert capscrews and star washers and tighten to specified torque.
2. Position brake lever on backing plate.
3. Position brake shoes on backing plate with actuating pawl in web slot.
4. Hook up brake shoe return springs.
5. Slide brake hub over splines of front output gear. Install retaining ring.
6. Install brake drum. Tighten capscrews to specified torque and lock with wire.
7. Install expansion plugs. The smaller plug goes in the bore of the front output gear and the larger in the brake drum.

Install Shift Shafts

1. If necessary, install new shift shaft oil seals in case.
2. Position declutch fork in collar.
3. Grease declutch shift shaft and slide it into case and through fork.
4. With shift shaft in position, insert and tighten set screw and lock with wire.
5. Position range shift fork in sliding gear.
6. Slide range shift shaft through fork. Install and tighten set screw and lock with wire.
7. Install expansion plugs at rear of case.
8. Place detent balls and springs in case.
9. Install cover with new gasket and tighten capscrews to specified torque.
10. Install P.T.O. with new gasket.
11. Install yokes or flanges and nuts and torque to specifications.

Lubrication

Install drain plug. Turn transfer case upright and pour ½ pint of recommended gear lubricant through filler plug opening. Add some oil to P.T.O. Do not fill unit to specified level until it is installed in the vehicle.

HYDRAULIC BRAKE SYSTEM

The hydraulic system used to actuate the brake mechanism consists of a compensating type master cylinder in which the hydraulic pressure is originated, individual wheel cylinders in which the hydraulic pressure is applied to actuate the brake shoes against the brake drums, and the fluid lines consisting of steel tubing, flexible hose, brackets and unions interconnecting the master cylinder and wheel cylinders. The master cylinder and wheel cylinders are fitted with pistons, all of which are provided with cup seals to maintain fluid pressure and prevent loss of brake fluid.

Depressing the brake pedal moves the piston within the master cylinder, thus displacing the brake fluid from the master cylinder through its outlet orifices, tubing and flexible hose connections into the wheel cylinders. The brake fluid, being non-compressible, enters each of the wheel cylinders, causing the cylinder pistons to move outward and actuate the brake shoes. As pressure on the pedal is increased, greater hydraulic pressure is built up within the wheel cylinders, and consequently greater force is exerted against the shoes.

When the pressure of the pedal is released, the brake shoe retracting springs return the brake shoes to their normal or released position. The return movement of the brake shoes, in turn, causes movement of the wheel cylinder pistons toward their released position, thus forcing the fluid back through the tubing into the master cylinder.

Fig. 1 Typical master cylinder

Hydraulic Fluid

Always use heavy duty hydraulic brake fluid. The use of other types of fluid or the introduction of mineral base oil into the system will cause rubber parts to swell and become inoperative.

Master Cylinders

The typical master cylinder consists of the components shown in Figs. 1 and 2. The fluid reservoir or supply tank is cast integrally over the master cylinder barrel. A combination filler and breather plug permits atmospheric pressure on the reserve fluid at all times.

Depression of the brake pedal causes the piston and cup to move forward in the cylinder barrel. A slight forward movement of the cup closes the compensating port and the pressure stroke commences. Actual pressure is not built up until the displaced fluid has caused all brake shoes to make contact with their brake drums. Additional pressure on the pedal produces hydraulic pressure within the brake system.

Release of the brake pedal after each brake application permits the brake pedal and push rod to return independently to their off positions. The return of the piston and cup is accomplished by the piston return spring.

The piston for this type of unit is designed to carry a primary cup and a secondary cup. The construction of the piston is such that reserve fluid from the tank passes through a vent in a recessed area. Thus we have fluid on both sides of the primary cup. The secondary cup is merely a seal to prevent loss of reserve fluid into the boot.

These master cylinders are also known as the compensating type. Its primary compensating function is to maintain a constant volume of fluid in the system at all times, regardless of expansion caused by heat, or contraction caused by cold. The secondary compensating function is the replacement of additional fluid into the system to counterbalance any loss due to gravity seepage.

The return to the off position of the piston and cup is much faster in displaced volume than the return of the fluid through the fitting into the master cylinder. A momentary vacuum is created in the cylinder barrel and additional fluid is drawn into the system through drilled holes in the piston and past the lip of the cup. The operating fluid returns more slowly from the wheel cylinders and lines back into the master cylinder barrel. Thus the master cylinder is full of fluid for the next brake application.

Fig. 2 illustrates a master cylinder with a bleeder valve located in the cylinder barrel. This bleeder valve is commonly used in the larger stroke master cylinders. Its purpose is to expell any air that may be trapped in the upper head end of the cylinder barrel.

Fig. 2 Master cylinder with bleeder valve. This unit does not have a double check valve as it is used with a vacuum power cylinder having this type valve

Master Cylinder Check Valve

A double check valve is used in all master cylinders of the compensating type. It is held in the closed end of the master cylinder barrel by the piston cup return spring. The valve performs two functions:

1. It acts as a seal to prevent fluid or air being drawn into the system through the bleeder screw during the bleeding operation. Fluid passed

Fig. 3 Single piston type wheel cylinder

through the valve on the pressure stroke can return into the master cylinder barrel only by raising the entire valve from its seat. The valve is held in place by the cup return spring.

2. When the pressure on the returning fluid drops below 6 to 8 pounds, the spring closes the valve and the system is under a slight pressure. This pressure will not cause the brake shoes to drag; it is used to assure a positive seal at the wheel cylinder cups. The valve does not control brake pedal movement. *Do not try to remedy this complaint by changing the valve.*

Note

On vehicles equipped with certain models of power cylinders, the check valve is located in the power cylinder slave cylinder tube. Where this is the case, no check valve is used in the master cylinder.

Wheel Cylinders

Two types of wheel cylinders are used in the hydraulic brake system. Different combinations of these two types of cylinders are used on different model vehicles. Fig. 3 illustrates a single piston wheel cylinder, and Fig. 4 shows a double piston type. The wheel cylinder is the unit that changes the applied hydraulic pressure into mechanical force to actuate the brake shoes.

Master & Wheel Cylinder Repairs

It is possible to rehone the majority of cylinders and place them in good working order. However, this requires the use of honing equipment and plug gauges, which are available through auto parts jobbers.

Cylinders and parts should not be washed in gasoline, kerosene or oil. Use high grade denatured alcohol.

Fluid Level

Inspect the master cylinder at the time of making brake adjustments. Fluid should be within ¾" from the top of the filler neck. Do not fill the supply reservoir to the top of the filler neck. When removing the filler cap, extreme care must be used to prevent dirt or moisture from entering the master cylinder.

Brake Pedal Adjustment

When the brake control system is in the release position, the foot brake pedal should have ¼" free travel before the pressure stroke starts. This free travel is required to prevent blocking of the compensating port in the master cylinder. *Brakes will drag if the compensating port becomes blocked due to pressure building up in the system.* Shorten the pedal push rod to allow the piston to uncover the compensating port, allowing fluid to escape into the reservoir.

Bleeding the Lines

Any air inside the hydraulic system must be removed. Whenever a line has been disconnected at the master cylinder, the entire system must be bled at all wheels until all air is completely expelled. When a line has been disconnected at any wheel cylinder, this cylinder together with the cylinder on the opposite wheel must be bled. Air in the system will cause a springy, rubbery action of the brake pedal. Should a sufficient quantity of air be introduced into the system, the brake pedal will go to the toe-board under normal pressure.

Fill the master cylinder reservoir with heavy duty brake fluid and see that it is kept at least half-full during the entire bleeding operation.

Vehicles equipped with brake booster units (vacuum and "Air-Pak" cylinders) require bleeding these units before any other units of the hydraulic system is bled. Figs. 5 to 10 illustrate the location of the bleeder valves on the various vacuum and air-pak units. See *Brake Booster* chapter for repairs on these units.

Bleeding Instructions

Bleed the power cylinder and wheel cylinders with the engine stopped. If the master cylinder has a bleeder valve, bleed it first before bleeding the wheel cylinders. If equipped with a power cylinder, bleed the power cylinder first at the control valve (No. 1) and then in the slave cylinder (No. 2) as shown in the illustrations. The procedure is as follows:

1. Attach bleeder tube (rubber) to bleeder valve No. 1. Insert end of tube into a clean glass jar containing a small amount of brake fluid.
2. Unscrew bleeder valve ¾ turn and depress brake pedal by hand. Allow pedal to return to the off position.
3. Repeat bleeding operation at bleeder valve No. 2.
4. Finally, bleed the wheel cylinders in any convenient order.

Fig. 4 Double piston type wheel cylinder

Fig. 5 Single 6¾" diameter piston power cylinder with integral air cleaner

Fig. 6 Single 6¾" diameter piston power cylinder ("C" Series)

Service Note

Bleeding instructions for all vehicles having a check valve in the master cylinder are to allow the pedal to return to the off position *slowly*. However, in brake systems where the check valve is located in the slave cylinder end of the power cylinder, the pedal must be allowed to *snap back quickly*. This rapid return of the pedal allows the master cylinder barrel to receive brake fluid from the master cylinder reservoir on the return stroke and not just draw the fluid back out of the lines when the pedal is released.

Pumping the pedal forces fluid into the glass jar and carries with it any air that might be in the system. Watch the flow of fluid from the tube, the end of which should be kept below the surface of the fluid in the jar. When all air bubbles cease to appear, or when the stream is a solid fluid mass, close the bleeder valve.

Fluid withdrawn in the bleeding operation should not be used again. Fluid should be replenished in the reservoir after each valve is bled. Should the reservoir be drained during the bleeding operation, air will enter the system and the bleeding operation will have to be repeated.

HYDRAULIC BRAKE SYSTEM

Fig. 7 Single 9½" diameter piston power cylinder ("C" Series)

Fig. 8 Tandem 9½" diameter piston power cylinder ("C" Series)

BRAKE TROUBLE DIAGNOSIS

Pedal Goes to Floor

1. Normal wear of lining.
2. Brakes not properly adjusted.
3. Leak in system.
4. Air in system.
5. Pedal improperly set.
6. No fluid in reservoir.

All Brakes Drag

1. Mineral oil in system.
2. Pedal improperly set.

One Wheel Drags

1. Weak brake shoe return spring.
2. Brake shoe set too close to drum.
3. Piston cups distorted.
4. Loose wheel bearings.

Fig. 9 Diaphragm type power cylinder. Note that only one bleeder valve is used

Pulls to One Side

1. Grease-soaked lining.
2. Shoes improperly set.
3. Backing plate loose on axles.
4. Front spring U-bolts loose.
5. Different makes of lining.
6. Tires not properly inflated.

Springy, Spongy Pedal

1. Brakes not properly adjusted.
2. Air in system.

Excessive Pressure On Pedal, Poor Stop

1. Brakes not properly adjusted.
2. Improper lining.
3. Oil in lining.
4. Lining making partial contact.

Light Pressure On Pedal, Severe Brakes

1. Brakes not properly adjusted.
2. Loose backing plates on axles.
3. Grease-soaked lining.

BRAKE ADJUSTMENTS

BENDIX DUO-SERVO BRAKE

This type brake, Fig. 1, is self-energizing in both forward and reverse. Each brake has one wheel cylinder mounted at the top of the backing plate below the single anchor pin. The anchor pin holds the wheel cylinder in place, being inserted through a flange on the wheel cylinder casting. Shoe return springs hold the upper end of the shoes against the pin with the brakes released. A guide plate, installed on the anchor pin outside of the shoe webs, holds the upper end of the shoes in alignment. Brake shoe lower guides, riveted to the backing plate, are also used on some models.

Brake adjustment is made at the adjusting screw in the adjusting link assembly. The link spring holds the shoe ends in place in the link ends. The link spring also serves as a lock for the notched adjusting screw.

Each brake shoe is held against three

Fig. 1 Bendix duo-servo single anchor brake with star wheel adjuster

bearing surfaces on the backing plate by the hold-down pins and springs. Lining on the secondary (rear) shoe is longer than the lining on the primary (front) shoe.

Unless the vehicle has a transmission parking brake, the rear brake assemblies have a parking brake lever attached by a cable to the secondary shoes. A strut between the primary and secondary shoes assures braking action by both shoes. Parking brake action is entirely mechanical and operates independently of the hydraulic brake system.

Adjustment, Fig. 1

Before attempting to make any adjustments, be sure the wheel bearings are properly adjusted and that the brake backing plates are tight.

1. Jack up wheels clear of floor and release parking brake.
2. Remove adjusting hole covers.
3. Insert screwdriver or special adjusting tool in slot of backing plate to engage star wheel adjusting screw.
4. Move outer end of tool toward axle, expanding brake shoes to a point where the wheel can just be turned by hand.
5. Parking brake cable (if used) adjustment should be made at this time. With brake shoes still expanded, disconnect parking brake cable at intermediate lever end. With parking brake lever applied approximately one inch from fully released position, pull cables by hand to remove all slack. Then adjust cables as required at yoke ends so that clevis pins can be inserted.
6. Back off star wheel adjusting screw until brake drums turn freely. It may be necessary to tap the backing plate lightly to permit brake shoes to assume a central position.
7. Pull parking brake lever back until rear wheel can just be turned by hand. Check rear wheels for equal brake drag. If drag is unequal, loosen the tight brake until drag is equal on both rear wheels.

Anchor Pin Adjustment

On some models, an adjustable anchor pin is provided for when brakes have been relined or when brake action is unequal or severe. Some vehicles have the adjustable anchor on all four brake assemblies while others have it on the front wheels only.

1. Loosen nut on anchor pin at inner side of backing plate, then retighten nut ¼ turn beyond finger-tight.
2. Remove adjusting hole cover from backing plate and turn star wheel adjuster to expand brake shoes until a heavy drag is felt when turning the brake drum by hand.
3. While continuing to expand shoes, periodically tap backing plate adjacent to the anchor pin to cause the anchor pin to center itself. When brake drag can no longer be relieved by tapping on the backing plate, hold anchor pin and tighten lock nut securely.
4. Back off star wheel adjuster just enough to eliminate brake drag. After adjustment is completed, install adjusting hole covers.

Fig. 2 Bendix uni-servo single anchor brake with star wheel adjuster

BENDIX UNI-SERVO BRAKE

This type brake, Fig. 2, is essentially the same as the duo-servo type except that a single end wheel cylinder is used instead of the double end type shown in Fig. 1. Adjustments are also the same as outlined for the duo-servo type.

It should be noted that some models of this type brake had the wheel cylinder mounted on the side of the assembly instead of the top as shown in Fig. 2.

BENDIX NON-SERVO BRAKE

This type brake, Fig. 3, has the upper end of the shoes extending through the wheel cylinder boots and contacting inserts in the wheel cylinder pistons. The shoe ends are held firmly against the pistons by the brake shoe return springs. The lower end of the shoes are held against a fixed anchor plate by the anchor spring. A hold-down spring at the center of each shoe holds the shoes in alignment. An eccentric adjustment located near the center of each shoe provides a means of compensating for lining wear and is the only shoe adjustment required.

Adjustment

1. With wheels raised clear of floor and hand brake released, turn forward shoe adjusting cam until a heavy drag occurs. Then turn the cam in the opposite direction until the drum is just free of drag.
2. Repeat with the rear shoe.

TIMKEN "DH" BRAKE

This brake, Fig. 4, commonly referred to as the Duplex Brake, is an hydraulically-actuated dual primary assembly. It features identical shoe and liner assemblies and four identical return springs which simplify assembly and disassembly, Fig. 5.

Fig. 3 Bendix non-servo brake of the floating shoe type with an eccentric cam adjustment for each shoe

Fig. 4 Timken "DH" series brake

Fig. 5 Timken "DH" series brake components

Adjustment

Brake is adjusted from the back face of the backing plate at the slotted holes. Insert screwdriver through slotted hole against ratchet lugs of adjusting bolts and move end of handle up or down as a lever, depending on rotation desired.

Shoe liners should be brought out against the brake drum until a slight drag can be felt while the drum is in rotation. Adjusting bolt should then be backed off until drum can rotate freely. Brake shoes should be adjusted individually.

TIMKEN "FSH" BRAKE

This brake, Fig. 6, is a floating shoe hydraulic assembly. Actuation permits the shoes to center themselves in the drum with equal effectiveness in either direction. This brake is supplied either with or without a built-in mechanical parking brake.

This brake is also built with automatic adjustment for use on special applications. On the automatic type, one actu-

Fig. 6 Timken "FSH" series brake

Fig. 7 Timken "FSH" series brake components. When not equipped with the parking lever feature, an upper coil spring is generally used rather than the "U" spring

Fig. 8 Timken "H" series brake

Fig. 11 Timken "T" series air actuated brake with cam follower wear pads

ation of the foot pedal sets the automatic adjustment. No further adjustment of the brake is required during the life of the brake lining. Fig. 7 shows the components that make up the assembly.

Adjustment

The adjustable type brake has two eccentric cams that may be adjusted with a wrench on the adjusting bolts at the back face of the backing plate.

Upon reassembly, first actuate the brake to center the shoes in the drum. Then adjust the liners out until a slight drag can be felt while the drum is in rotation. Back off the adjusting bolt until the drum can rotate freely.

Subsequent adjustments to compensate for lining wear may be made by moving the shoe in or out by turning the eccentric cam in the required direction.

TIMKEN "H" BRAKE

This brake, Fig. 8, is a light duty, two shoe type mounted on the backing plate which also serves as a dust shield. Adjustable anchor pins provide a means of centering the brake shoe arc in relation to the drum. Secondary or minor adjustments are made by rotating the eccentric cam which bears on the brake shoe flange or pin in the shoe web.

Adjustment

Following overhaul or when new linings are installed, the initial adjustment should be carefully made to locate properly the curvature of the lining to the drum and to obtain the proper clearance.

Each shoe must be adjusted to center the brake shoe arc in relation to the drum. Back off on both anchor pins and cams and adjust each shoe individually.

Adjust cam to bring lining into contact with drum and rotate anchor in enough to relieve drag. Repeat until additional rotation of anchor pin will no longer relieve drag, Fig. 9. Lock anchor pin lock nut and back off cam just enough to permit wheel to turn freely.

Subsequent adjustments to compensate for lining wear are made with the eccentric cam only. Turn cam to bring lining into contact with drum. Then back off just enough to permit free rolling drum. Repeat on opposite shoe.

TIMKEN "T" BRAKE

The "T" series brake, Fig. 10, is an air actuated two shoe brake, each shoe employing a one piece liner of uniform thickness. These brakes are either unit mounted with all component parts assembled on a backing plate or spider, or have inboard cam supports where operation warrants locating the air chambers toward the axle centers.

Some sizes of "T" brakes employ fabricated shoes with hardened steel cam roller followers Fig. 10, while other sizes employ either heat-treated malleable cast shoes with hardened cam follower wear pads, Fig. 11, or cam roller followers. Anchor pins of two different designs are used in various sizes of "T" series brakes. Some sizes use eccentric pins while others use fixed anchor pins.

The "T" series brakes are equipped with enclosed adjustable levers when shoe liner thickness does not exceed ⅜". The enclosed adjustable lever on these will permit the maximum liner wear. "T" series brakes with thicker liners, up to and including ½", are equipped with

Fig. 9 Timken "H" series brake adjustments

Fig. 10 Timken "T" series air actuated brake with cam roller followers

Fig. 12 Timken "T" series brake components

Fig. 13 Timken "P" series brake

slack adjusters. Fig. 12 illustrates the component parts of the assembly.

Adjustment

On the "T" Fabricated Steel Brake, each shoe must be adjusted to center the brake shoe arc with the drum.

1. Rotate both anchor pins to the full release position.
2. Adjust cam to bring the liners in with drum and rotate anchor pins just enough to relieve drag. Repeat until additional rotation of anchor pins will no longer free drag.
3. Tighten anchor pin lock nuts and back off cam to minimum running clearance. To compensate for liner wear on both the fabricated steel and the cast assemblies, adjust cam at cam lever adjusting bolt to bring liners in contact with drum and back off to minimum running clearance.

TIMKEN "P" BRAKE

The automotive "P" series brake is an air actuated two shoe brake, each shoe employing two ¾" tapered block liners, Fig. 13. These shoes are fabricated steel, mounted on individual anchor pins and supported by open type spiders. The air chamber mounts on a bracket that bolts directly to the spider, thus making the brake completely unit mounted.

Automotive "P" series brakes may also be equipped with inboard cam supports where operation or axle design requires mounting the air chambers toward the axle centers. Dust shields are available for use when protection becomes desirable.

The "P" series brakes are actuated by "S" type constant lift cams which are forged integrally with shaft and supported in nylon bushings. Cam pressure is applied by cam roller followers. Fig. 14 shows the brake components.

Adjustment

New liners should be circle ground to .070" less than drum diameter. Adjust cam as required to obtain 80% contact.

Adjust slack adjusters or levers to obtain ¾" travel at 60 lbs. pressure. When travel increases to 1½" due to wear, readjust to ¾".

Fig. 14 Timken "P" series brake components

Fig. 15 Timken "P" series heavy duty brake

TIMKEN HEAVY DUTY "P" BRAKE

The Heavy Duty "P" series brake, Fig. 15, is an air actuated two shoe brake designed for heavy duty and special equipment where greater shoe and drum areas are necessary. This heavy duty series ranges from 18″ to 22″ and in width from 4″ to 7″.

The shoes are of heat treated malleable castings mounted on open spiders by individual anchor pins. Each shoe has hardened cam pressure pads and employs two ¾″ tapered block liners.

The camshaft and air chamber support bracket is mounted directly on the brake spider, making the assembly complete as a unit. However, the heavy duty brake may also be equipped with inboard cam supports where operation or axle design requires mounting the air chambers toward the axle centers.

Cam pressure is applied to the shoe hardened wear pads through the double "S" cam which is supported in needle bearings. Fig. 16 illustrates the component parts of the brake assembly.

Adjustment

New liners should be circle ground to .070″ less than the drum diameter. Adjust cam as required to obtain 80% contact.

Adjust slack adjusters or levers to obtain ¾″ travel at 60 lbs. pressure. When travel increases to 1½″ due to wear, readjust to ¾″.

WAGNER NON-SERVO BRAKE

This type brake, Fig. 17, has an adjustable anchor pin and an eccentric cam for each shoe. Note that the brake shown has a stepped type hydraulic cylinder with one end smaller than the other. However, other models have both ends of the cylinder the same diameter.

Minor Adjustment

1. With wheels raised clear of floor and hand brake in released position, rotate cam "A" outward until front shoe contacts drum and a definite drag is felt when wheel is turned by hand. Then back off adjustment until wheel is free.
2. Repeat procedure with cam "B".

Major Adjustment

1. With wheels and drums installed, rotate cam "A" until there is a brake drag felt when wheel is turned by hand.
2. Turn shoe anchor "C" in the direction of forward rotation of the wheel until a definite brake drag is felt. Note position of the anchor. Turn anchor "C" back in the opposite

Fig. 16 Timken heavy duty "P" series brake components

Fig. 17 Wagner brake with two adjustable anchor pins and an eccentric cam adjustment for each shoe

direction until the same amount of brake drag is felt and again note the position of the anchor. Then turn anchor "C" back until it is halfway between the two extremes, producing a free wheel. This will indicate that the shoe is roughly centralized.

3. Check both toe and heel of the shoe with a feeler gauge to determine the next steps to be taken in moving the adjustments.
4. Adjust cam "A" and anchor "C" until a clearance of .005″ is obtained at the heel and a clearance of .010″ is obtained at the toe end of the shoe as measured about 1½″ from ends of lining.
5. Tighten lock nut on anchor "C" securely. Recheck clearances at shoe ends to make sure adjustments have not altered.
6. Repeat the foregoing operations on the rear shoe by adjusting cam "B" and anchor "D", substituting the word reverse for the word forward.

WAGNER "F" BRAKE

This type brake, Fig. 18, is self-centering and has two identical brake shoes arranged on the backing plate so that their toes are diagonally opposite. Two single end hydraulic cylinders are arranged so that one cylinder is mounted between each shoe toe and the opposite shoe heel.

The two hydraulic cylinder pistons apply equal amounts of hydraulic force to each shoe toe. Each cylinder body is shaped to provide an anchor block for the opposite shoe heel. Each cylinder anchor block serves as a shoe stop centering point and provides the fulcrum around which the shoe heel pivots when the brakes are applied.

Fig. 18 Wagner "F" type brake. It should be noted that some models have the wheel cylinders mounted near the top and bottom of the assembly with the adjusting cams located at the sides

Fig. 19 Wagner twin action brake. Some models have the wheel cylinders mounted at approximately the 5 and 11 o'clock positions. Also, some have brake shoe retracting springs of unequal lengths

Adjustment

1. With wheels jacked clear of floor, place wrench on one adjusting cam stud to adjust one shoe. Rotate wrench in the direction of forward wheel rotation until lining drags on drum.
2. Move wrench slightly in opposite direction until wheel is free to turn; then move wrench an additional 7 to 10 degrees to provide running clearance (7 to 10 degrees is equal to 1″ to 1½″ of travel at end of an 8-inch wrench).
3. Place wrench on opposite adjusting cam stud and adjust second shoe in the same manner.

WAGNER TWIN ACTION BRAKE

This type brake, Fig. 19, is equipped with two double end hydraulic cylinders

which apply hydraulic pressure to both the toe and heel of two identical, self-centering shoes. The shoes anchor at either toe or heel, depending upon the direction of drum rotation. Brake anchor supports and backing plates are riveted to the axle housing flange. The supports have slotted anchor pins at the shoe heels, and adjusting screws at the shoe toes. The adjusting screws act as anchors in the reverse direction of rotation. Each adjusting screw is threaded into or out of its support by means of an adjusting wheel. The adjusting wheels are accessible through slots in the backing plate.

Adjustment

1. With wheels raised clear of floor, remove adjusting hole covers from backing plate.
2. Use a screwdriver or special adjusting tool through opening in backing plate and turn rear adjusting screw until a light drag is felt as wheel is turned. Then back off until drum turns freely.
3. Repeat adjustment at front adjusting screw. Install adjusting hole covers.

AIR BRAKES

Trouble Diagnosis 267

AIR BRAKE EQUIPMENT

Air brake equipment on trucks and truck tractors provides a means of controlling the brakes through the medium of compressed air. The equipment consists of a group of devices as shown in Fig. 1. Some of these devices maintain a supply of compressed air, some direct and control the flow of compressed air, and others transfer the energy of compressed air into the mechanical force and motion necessary to apply the brakes.

Different sizes and types of devices are in use on different types of vehicles to meet operating requirements. Following are the devices comprising a typical air brake system with a brief description of the function of each device.

Air Compressor

The compressor supplies the compressed air to operate the brakes. Two types are in general use, the piston type and the rotary type. Both types run continuously while the engine is operating.

In the piston type, Figs. 2 and 3, the actual compression of air is controlled by the governor which, acting in conjunction with the unloading mechanism in the compressor cylinder block, starts and stops the compression of air by loading or unloading the compressor when the pressure in the air brake system reaches the desired minimum of 80-85 psi or maximum of 100-105 psi.

In the rotary type, Figs. 4 and 5, the actual compression of air is regulated by the control valve (governor) which starts or stops air compression by "loading" or "unloading" the compressor as required. This action establishes an intermittent pumping cycle which keeps reservoir tank pressure within the desired range.

Fig. 2 Piston type air compressor

Governor

With piston type compressors two types of governors are in general use, the diaphragm type and the bourdon tube type.

The diaphragm type, Fig. 6, acting in conjunction with the compressor unloading mechanism, automatically limits system pressure to a predetermined range by opening unloading valves and stopping compression when system pressure has been built up to a maximum of 100-105 lbs, and by closing unloading valves and starting compression when system pressure has dropped to a minimum of 80-85 lbs. The governor consists essentially of a diaphragm upon which air pressure acts, a spring to control the movement of the diaphragm, and a valve mechanism controlled by the position of the diaphragm which admits air to, or exhausts air from, the unloading mechanism in the compressor cylinder heads.

The design of the type governor shown in Fig. 7 is based on the principle of the bourdon tube. This is a flattened metal tube bent to a curve that tends to straighten under internal pressure. This reaction by the tube, due to changes of air pressure in the tube, increases or decreases the spring load on the valve mechanism of the governor and makes the valve mechanism assume its "cut-in" or "cut-out" positions in accordance with the air pressure in the reservoir tank.

The control valve (governor) for rotary type compressors regulates the pumping action of the compressor to

Fig. 1 Typical air brake system circuit diagram

maintain the correct pressure range in the reservoir tank.

Brake Application

The brake application valve controls the air pressure being delivered to the brake chambers and in this way controls the operation of the brakes.

Fig. 8 illustrates the integral treadle type while Fig. 9 shows the lever type which is fastened to a brake pedal or treadle.

The hand control valve, Fig. 10, is used for controlling the brakes on a trailer independently of the brakes on the towing truck. The valve is usually mounted on the steering column or on the dash and the driver may put the handle in any one of several positions between "brakes released" and "brakes applied" position so the brakes on the trailer are kept applied until the brake valve handle is returned to release position.

Relay Valve

The relay valve, Fig. 11, speeds up the application and release of air pressure from the rear wheel brake chambers. It is controlled by the brake application valve and keeps the air pressure in the rear wheel brake chambers the same as the pressure being delivered by the brake application valve. It reacts to even slight changes in pressure and raises, lowers, or completely exhausts the air pressure in

Fig. 3 Side-mounted piston type air compressor

Fig. 4 Rotary type air compressor

the rear brake chambers as the brake application valve raises, lowers, or completely exhausts air pressure from it.

Rear Brake Balancing Valve

Used on late model GMC trucks, this valve is used to vary the degree of rear brake application as load on rear axle varies, Fig. 11A. A light load, for example, requires lighter brake pressure to avoid locking wheels and losing traction.

The balancing valve is located near the frame rear crossmember. It is installed in the air line between the brake application valve and the rear brake relay valve.

The balancing valve assumes three positions during normal operation. In the applying position, the air pressure is passing through the valve into the rear brake relay valve. In the holding position, the air pressure is held in the relay valve and in the rear brake chambers. In the releasing position, the control air is exhausted through the application valve and the brake chamber air is exhausted through the relay valve. Air pressure beneath the diaphragm changes only as the height control valve meters air into or out of the bellows.

Fig. 6 Diaphragm type governor used with piston type air compressor

Fig. 5 Rotor and stator of rotary type air compressor

Fig. 7 Bourdon tube type governor used with piston type air compressor

Quick Release Valve

The purpose of the quick release valve, Fig. 12, is to reduce the time required to release the brakes by hastening the exhaust of air pressure from the brake chambers. It is commonly used with front wheel brake chambers.

The valve consists of a body containing a spring-loaded diaphragm so arranged as to permit air pressure to flow through the valve in one direction. But when the supply pressure is reduced, the air which has passed through the valve is permitted to escape through the exhaust port.

Brake Chambers

Brake chambers, roto chambers or brake cylinders transform the energy of compressed air into the mechanical force and motion necessary to apply the brakes. One of these units is used to operate the brakes on each wheel.

The diaphragm type, Fig. 13, consists of two dished metal plates, namely the non-pressure plate and the pressure plate, and the pressure plate separated by the diaphragm. In front of the diaphragm are the non-pressure plate, push rod and push rod spring. Behind the diaphragm is the air-tight cavity into which is connected a tubing line from the brake application valve. Due to the extreme sensitivity of the diaphragm, this arrangement permits the push rod to respond to the slightest variation of air pressure from the brake application valve, thus permitting the driver to apply or release brakes as rapidly or gradually as the various road and operating conditions warrant. In order to meet requirements for different braking forces, brake chambers are made in several different sizes. All sizes are made for several different types of mountings, such as stud mounting, bracket mounting and flange mounting.

The piston type brake chamber, Fig. 14, operates in much the same manner as the diaphragm type just described.

A roto brake chamber is shown in Fig. 15. The major parts are a cylindrical body, tubular diaphragm, inner and outer diaphragm clamps, push rod, spring, cover, mounting studs and yoke. One end of the diaphragm is connected to the inside wall of the body by the outer clamp. The push rod is attached to a push plate and the assembly is attached to the diaphragm guide. The cover is attached to the outer body and a yoke is screwed onto the end of the push rod, completing the roto chamber assembly.

Slack Adjusters

Slack adjusters, Fig. 16, provide a quick and easy method of adjusting the brakes to compensate for brake lining wear. One slack adjuster is used for the brakes on each wheel. Slack adjusters consist of a worm and gear enclosed in a body which serves as an adjustable lever. During brake application, the entire slack adjuster rotates bodily with the brake camshaft. During brake adjustment, the worm moves the gear so as to change the

Fig. 8 Brake application valve with integral treadle

Fig. 9 Lever type brake application valve which fastens to a brake pedal or treadle

Fig. 10 Hand operated brake application valve for trailer brakes

position of the lever arm in relation to the brake camshaft.

Fig. 17 illustrates the locking sleeve in its disengaged position. Be sure this is *held in,* disengaging the adjusting screw, when making adjustments. *Never use a wrench on the sleeve portion.*

When slack adjuster movement does not give the desired brake action, adjustment of the push rod length by altering the location of the yoke may be necessary. With brakes released the angle formed by the push rod and slack adjuster must be greater than 90 deg., and all slack adjusters must be set at the same angle. With the brakes fully applied, after being adjusted, this angle should still be greater than 90 deg., Fig. 18.

Cut-Out Cocks

Cut-out cocks are used in the service and emergency lines of the tractor-truck to provide a means of closing off these lines when they are not being used.

Always open and close a cut-out cock by hand. Never strike the handle with a hammer or similar instrument as the cock will be damaged and leakage will develop.

Air Reservoirs

The purpose of the reservoirs is to provide a place to store compressed air so that there will be an ample supply available for immediate use in brake operation. They also provide storage for sufficient compressed air to permit several brake applications after the engine has stopped. Another function of a reservoir is to provide a place where the air, heated during compression, may cool and cause the oil and water vapors to condense.

Drain Cocks

Drain cocks are installed in the bottom of each reservoir, Fig. 19, in the air brake system to provide a convenient means of draining the condensation which normally collects in the reservoirs.

Always open a drain cock by hand. Never strike the handle with a hammer or similar instrument as the cock will be damaged and develop a leak.

Safety Valve

The purpose of the safety valve, Fig. 20, is to protect the air brake system against excessive air pressure. Should the air pressure in system rise above the setting of the safety valve at 150 lbs., the valve opens and permits the excess pressure to be exhausted. The valve consists of a spring-loaded ball check valve which is set to "blow off" at 150 lbs. air pressure.

Low Pressure Indicator

The low pressure indicator, Fig. 21, is a safety device designed to give an automatic warning whenever the air pressure in the system is below approximately 60 lbs. Operating as an air-controlled switch of an electrical circuit, the low pressure indicator automatically sounds a buzzer when the air pressure drops too low. On

Fig. 11A Rear brake balancing valve (GMC)

some vehicles a light is used to indicate low pressure in place of the buzzer.

Double Check Valve

Double check valves are used in an air brake system where it is necessary to automatically direct the flow of air pressure into a common line from either of two lines.

There are two types of double check valves, the shuttle type shown in Fig. 22, and the disc type.

The shuttle type consists of a die cast body and two end caps. Inside the valve

Fig. 12 Quick release valve used for operation of front wheel brakes

Fig. 11 Relay valve for rear wheel brake operation

Fig. 13 Diaphragm type brake chamber

Fig. 14 Piston type brake chamber

Fig. 15 Roto brake chamber

Fig. 16 Slack adjuster

Fig. 17 Locking sleeve on adjusting nut of slack adjuster

are two rubber seal gaskets and a brass metal shuttle.

The disc type consists of a cast body and one end cap. Inside the valve is a rubber disc and a disc guide. One end of the end cap serves as a disc seat, the other end is tapped for air line connections.

Fundamentally, the only difference in the design of the two valves is that the shuttle type has a movable metal shuttle which contacts rubber seats to seal off the line not being used, whereas the disc type has a movable rubber disc which contacts metal seats.

Single Check Valve

The single check valve is a small device placed in an air line when it is important to allow air passage in one direction only and prevent passage in the reverse direction.

The check valve contains a spring-loaded disc which normally seats against the air inlet in one end of an inner chamber. Air flow in the normal direction moves the check valve from its seat and the flow is unobstructed. Flow in the reverse direction is prevented by the seating of the disc, which is caused by the action of the spring and assisted by the air pressure.

Tractor Protection and Two Way Valves

The purpose of the tractor protection valve, Fig. 23, is to provide extra brake protection for towing vehicles. It provides for complete braking control of the truck or tractor by permitting closure of service and emergency lines leading to the trailer hose lines in the event of a trailer breakaway or other malfunction in the tractor or trailer air brake system.

The manually controlled type consists of a two-way control valve, Fig. 24, and the tractor protection valve.

For all normal operating conditions the two-way control valve handle is placed in the normal position which permits reservoir pressure to enter the tractor protection valve and act on the diaphragm and plunger assembly. During initial charging, the emergency valve and service disc valve in the tractor protection valve remain closed until 30-40 lbs. air pressure is reached in the tractor reservoir and up to that pressure no air is supplied to the trailer through the trailer emergency line.

Fig. 18 Showing correct travel of slack adjuster when properly adjusted

When 30-40 lbs. air pressure is reached in the tractor reservoir, the emergency valve and service disc valve in the tractor protection valve open and remain open, allowing air pressure to be de-

Fig. 19 Reservoir, drain cock and safety valve

Fig. 22 Double check valve (shuttle type)

Fig. 20 Safety valve

Fig. 23 Tractor protection valve

Fig. 21 Low pressure indicator

livered through the emergency line charging the trailer reservoir. All normal braking and emergency functions for both truck-tractor and trailer are retained as long as the tractor reservoir pressure is above 30-40 lbs.

Air Supply Valve

In some cases the air supply valve is included to provide an easy means of obtaining compressed air from the air brake system for such purposes as tire inflation.

Air Pressure Gauge

The purpose of the dash-mounted air pressure gauge is to register the amount of air pressure in the system. While air pressure gauges of this type are commercially accurate, they must never be confused with or substituted for test gauges which are intended primarily for accurately checking air pressure in the air brake system.

Test gauges differ from ordinary dash gauges in respect to material and workmanship just as an expensive watch differs from a cheaper one. Due to these differences they are more accurate over the entire range and maintain their accuracy over longer periods.

Stop Light Switch

The stop light switch, Fig. 25, is mounted on or near the brake application valve. Stop light switches are electro-

Fig. 24 Toggle type two-way control valve (some vehicles use push button type)

Fig. 25 Stop light switch

pneumatic switches which close the stop light electrical circuit when the brakes are applied.

Alcohol Evaporator

On some vehicles an alcohol evaporator is included to prevent moisture freezing in the air brake system.

OPERATION TESTS

If the air brake system is not operating properly the following tests will help in locating the source of trouble.

Drain Reservoirs

With the air brake system charged, open the drain cocks in each reservoir. Close the drain cocks after all moisture is drained from reservoirs.

Check Stoplight Switch

With all air pressure exhausted from the air brake system, start the engine and move the brake valve to the applied position. Stop lights should light before the dash gauge registers 10 psi pressure. Release the brakes.

Low Pressure Indicator

Exhaust the brake system pressure and observe the pressure at which the warning buzzer sounds. The contacts in the indicator should close the circuit to the buzzer when reservoir pressure is between 54 psi minimum and 66 psi maximum. If the buzzer does not start to sound within this pressure range during discharge, or if the sounding buzzer does not stop within this pressure range during the pressure build-up, the electrical connections are loose or the indicator valve is defective.

Governor

With the engine running, build up air pressure in the system and observe at what pressure reading on the dash gauge the pressure stops climbing. This is the point of governor cutout, which should be between 100 and 105 pounds.

With the engine still running, slowly reduce the air pressure in the system by applying and releasing the brakes. Observe the pressure reading on the dash gauge at the point where the pressure starts to build up again. This is the point of governor cut-in which should be between 80 and 85 pounds.

If the governor does not cut the compressor in and out according to these specifications, adjust the governor pressure settings. Before adjusting the governor, check the accuracy of the dash gauge with a test gauge.

Quick Release Valve and Relay Valve

With the air brake system fully charged, apply the brakes. Inspect the brake action on the wheels controlled by the quick release valve or relay valve in question. The brakes should apply promptly. Release the brakes and inspect to be sure that the air pressure exhausted rapidly from the exhaust port. Be sure the exhaust port is not restricted.

Rear Brake Balancing Valve

In a serviceability test (without trailer), disconnect the air line to the brake chamber and attach an air pressure gauge. A light, easy brake application should register about 13 psi. The gauge pressure should not exceed 17 psi, however.

Reservoir Safety Valve

To determine if the safety valve is operative, pull the exposed end of the valve stem. If the safety valve does not "blow off" when the stem is pulled, the valve ball is probably stuck in its seat. In such a case, remove and disassemble the valve for cleaning.

Check Pressure Build Up

With the engine running at fast idle speed, observe the time required to raise system pressure from 50 to 90 pounds. If more than five minutes is required, perform the leak tests as outlined in the following paragraphs.

LEAK TESTS

With the engine stopped and brakes *released,* watch the rate of drop in air pressure as registered by dash gauge. If the pressure drops faster than two pounds per minute, check the items outlined under *Compressing System.*

With the engine stopped and brakes fully *applied,* watch the rate of drop in air pressure as registered by the dash gauge. If the pressure drops faster than three pounds per minute, check the items listed under *Braking System.*

Compressing System

Compressor—With the engine stopped, discharge valve leakage can be detected by carefully listening at the compressor for the sound of escaping air. With air pressure applied to the unloader cavity (with governor cut out) remove the air filter and check for air leaks by squirting oil around the unloader plunger and stem. If excessive air leaks are found, replace the unloader piston seal.

Governor—With the governor in the "cut-out" position, test for leakage at the exhaust valve by applying soap suds to the exhaust vent in the body.

With the governor in the "cut-in" position, test for leakage at the inlet valve by applying soap suds to the exhaust vent in the body.

In either of the foregoing tests, leaking in excess of a one-inch soap bubble in three seconds indicates a defective governor.

Coat the entire governor with soap suds to detect diaphragm, gasket and cap screw leakage. No leakage is permissible.

Safety Valve—Coat the end of the safety valve with soap suds. Leaks causing not more than a three-inch soap bubble in three seconds are permissible.

Braking System

Brake Valve—With the pedal fully released, coat the exhaust port with soap suds to check for leaks. With the pedal fully applied, coat the exhaust port with soap suds and check for leaks. Leaks causing not more than a three-inch bubble in three seconds are permissible.

Brake Chambers—With the brakes fully *applied,* coat the clamp ring and bolt flanges holding the diaphragm in place with soap suds. Coat the rubber boot with soap suds. No leaks are permissible.

Quick Release Valve—With brakes *applied,* coat the exhaust port with soap suds to detect leakage. Leakage in excess of a three-inch soap bubble in three seconds is permissible.

Relay Valve—With the brakes *released,* coat the exhaust port with soap suds and observe the leakage.

With brakes fully *applied,* coat the exhaust port with soap suds and observe the leakage.

Leakage in either of the foregoing tests should not exceed a three-inch soap bubble in three seconds.

Rear Brake Balancing Valve—Coat the valve with soap suds to test for leaks at connections and around the diaphragm at the clamp ring. Tighten connections or clamp ring as necessary to stop leaks.

With pressure gauge connected to the brake chamber, apply brakes and hold. If pressure gradually builds up toward full brake pressure, plunger seat is leaking. Leak may be caused by dirty seat groove, a worn or damaged seat, or an improperly installed seat.

TROUBLE DIAGNOSIS

This diagnosis lists the more common causes of brake problems and their possible causes.

Insufficient Braking Action

1. Low reservoir pressure.
2. Brakes need lubrication, adjustment or relining.
3. Foot control valve delivery pressure too low due to malfunction in the valve or incorrect adjustment of treadle linkage.

Slow Brake Application

1. Lack of lubrication at brake shoe camshafts.
2. Low reservoir pressure.
3. Excessive lubrication during brake application.
4. Restricted or damaged pipes or hoses.
5. Defective foot control valve and treadle linkage.

Slow Brake Release

1. Restricted port, weak return spring or other defect in foot control valve.

2. Brakes require lubrication or adjustment.
3. Restricted or damaged pipes or hoses.
4. Defective or restricted quick release valve or relay valve.
5. Broken retraction springs or binding hold pins.

Brakes Do Not Apply

1. Low reservoir pressure.
2. Restricted or broken pipes or hoses.
3. Defective foot control valve.

Brakes Do Not Release

1. Restricted brake lines.
2. Weak return spring or other defect in foot control valve.
3. Broken brake shoe retracting springs or rusted front anchor pins.

Brakes Grab

1. Grease on brake lining.
2. Out-of-round brake drums.
3. Bind in brake shoe mountings.
4. Defective foot control valve.
5. Wet brakes.

Uneven Brakes

1. Brakes need adjustment, lubrication or relining.
2. Grease on brake linings.
3. Out-of-round brake drums.
4. Leaking brake chambers.
5. Broken brake chamber piston return spring.
6. Wet brakes.

Air Pressure Will Not Rise To Normal

1. Defective air gauge.
2. Governor out of adjustment.
3. Compressor worn out.
4. Compressor discharge valve leaking.
5. Slipping compressor drive belt.
6. Open reservoir drain cock.
7. Excessive leakage at lines and fittings to reservoir tank.

Slow Air Pressure Build Up

1. Excessive air leakage.
2. Slipping compressor drive belt.
3. Low engine speed.
4. Worn out compressor.
5. Excessive carbon in compressor head or discharge line.
6. Compressor discharge valve leakage.
7. Clogged compressor air strainer.

Abnormal Air Pressure

1. Defective or improperly adjusted governor.
2. Restriction in passage between governor and compressor unloading mechanism.
3. Compressor inlet valves stuck closed.
4. Leak at compressor unloading piston seal.
5. Defective air gauge.
6. Carbon deposits in cavities beneath unloading piston and passages in compressor cylinder head.

Quick Air Pressure Drop With Brakes Released and Engine Stopped

1. Excessive leakage at foot control valve, governor, compressor discharge valve, or at other points in the system.

Quick Air Pressure Drop With Brakes Applied and Engine Stopped

1. Excessive leakage in brake chambers, brake chamber diaphragms, tube and hose connections, or foot control valve.

Continuous or Intermittent Compressor Knocks

1. Loose drive pulley.
2. Worn or burned out compressor bearings.
3. Excessive carbon deposits in compressor cylinder head.

Safety Valve "Blows Off"

1. Governor cut-out setting adjusted too high.
2. Above normal system pressure.
3. Defective or improperly adjusted safety valve.

Excessive Oil or Water In Brake System

1. Worn compressor piston rings.
2. Dirty compressor air strainer.
3. Failure to drain reservoirs at regular intervals.

BRAKE BOOSTERS

BENDIX HYDROVAC

The Hydrovac, Figs. 1 and 2, consists of three basic units which have been so combined that they function as a single unit, all of which are controlled by hydraulic pressure developed within the hydraulic master cylinder of the vehicle brake system. The three basic units are:

1. A hydraulically actuated vacuum control valve which controls the degree of brake application or release. The control valve consists of a hydraulic actuated piston, a diaphragm, and a vacuum and atmospheric poppet.
2. A vacuum power cylinder which contains either a single or tandem piston and a push rod that connects the vacuum piston to the hydraulic piston of the hydraulic cylinder.
3. A hydraulic slave cylinder which contains a piston with a check valve. Some models incorporate a residual line pressure check valve.

Operation

As the brake pedal is depressed, the hydraulic pressure developed within the master cylinder is transmitted to the hydraulic piston of the control valve and to the hydraulic cylinder. With pressure applied to the control valve piston, the vacuum valve closes and the atmospheric valve opens to admit air to the control side of the vacuum power cylinder. As air is admitted, the forces acting upon the vacuum power cylinder pistons are transmitted directly to the hydraulic piston through the push rod. As the hydraulic piston starts to move, the piston check valve closes, Fig. 3, trapping fluid under pressure ahead of the piston.

The total hydraulic pressure created and transmitted to the wheel cylinders is the sum of the pressure developed as a result of the vacuum power cylinder push rod thrust and the pressure received by the Hydrovac from the master cylinder.

As the brake pedal is released, the pressure within the control valve hydraulic piston chamber is reduced, allowing the atmospheric poppet to close and reopen the vacuum poppet. The vacuum power cylinder piston is again balanced in vacuum and returns to release position. When the hydraulic piston nears the release end of its stroke, its check valve reopens, Fig. 4, thus permitting the full release of the brakes.

Single Piston Types

Disassembly

Fig. 5. Loosen hose clamps (1) and (2) and slide hose off tube. Loosen lock nut (3) and unscrew hydraulic cylinder (4) from end plate. Hold end cap (7) in vise and unscrew hydraulic cylinder, using open-end wrench on flat part of cylinder. Remove gasket (5) and bleed screw (6) from end cap. If unit has a residual line pressure check valve (11), remove this valve by taking out snap ring (8), washer (9) and spring (10).

Fig. 6. Remove control valve housing and valve parts. Scribe a line across cylinder shell and end plate so these can be reassembled in their original position. Remove hook bolts and then cylinder shell.

Fig. 7. Compress piston return spring by pressing down on end plate and install hook clamps as shown (dimensional sketch shows how to make these clamps). Remove hydraulic piston (2) from push rod by sliding snap ring or retainer spring back and removing pin. Remove hook clamps which will allow vacuum piston and spring to come out. If vacuum piston leather or any other part of the piston is damaged, disassemble piston. Disassemble hydraulic piston

Fig. 1 Sectional view of Third Series Hydrovac with single piston

by first removing snap ring (1). Then remove spring cup, spring and ball.

Fig. 8. Place end plate over pins of end plate holding fixture (inset shows dimensions for making this fixture). Clamp fixture in vise. Remove retainer ring (4), using special tool T-25254, and stop washer (3). Using 1⅛" socket wrench, remove hydraulic valve piston fitting (2). Press out valve piston (1) and remove cup (or cups) from valve piston.

Fig. 9. Remove hydraulic cylinder end seal (3). Remove snap ring (2) and push rod seal cup parts. Lift end plate from fixture and place it upon two wooden blocks. Drive out push rod leather seal (1), using a flat end rod or drift.

NOTE—Immerse all metal parts in Bendix Metalclene Parts Cleaner. Dip all metal parts in the hydraulic system in alcohol before assembly. Use all parts furnished in the Hydrovac Repair Kit for the particular unit being serviced. Repair kits include new rubber parts. Old rubber parts should be discarded. If the bore of the vacuum cylinder shell is corroded or rusted, polish with fine emery cloth or steel wool; if badly pitted or scored, the shell should be replaced.

Assembly

Fig. 10. Press push rod leather seal into end plate with lip of leather toward hydraulic cylinder side of end plate. Assemble push rod hydraulic seal parts (1) as illustrated; stop washer (2) with chamfered side down, seal cup (3) with lip of cup up, retainer washer (4) with flat side next to cup, small end of spring

Fig. 3 Hydraulic check valve in applied position

Fig. 4 Hydraulic check valve in released position

Fig. 2 Sectional view of Third Series Hydrovac with tandem piston

Fig. 6 Disassembly of vacuum control valve

down. Place stop washer against spring and assemble snap ring in groove.

Fig. 11. Assemble stop washer (4) and retainer ring (5), using special tool T-25254. Dip piston cup or cups in brake fluid and assemble on piston (1). Insert piston into fitting (3) with hole end of piston next to stop washer (4). Place end plate on holding fixture. Use new copper gasket (2) on hydraulic fitting (3) without groove. Use new rubber seal gasket (2) on hydraulic fitting with groove. Assemble fitting into end plate and securely tighten with 1⅛" socket wrench. When copper gasket (2) is used, fitting (3) should be tightened to 1100-1300 inch-pounds of torque.

Fig. 20 Vacuum piston return spring compressing tool

Fig. 24 Disassembly of fast application valve seat and poppet

packing or other parts, reassemble piston and push rod as illustrated. Drill $\frac{5}{16}$" hole in bench and place push rod (10) in hole with threaded end up. Assemble piston parts as follows: Flat washer over threaded end of push rod. Larger diameter piston plate (7) with chamfered side of hole up. Guide rubber seal ring (6) over threads. Place assembly ring (8) of correct size over piston plate and assemble following parts: Leather packing (5) with lip of packing up; smaller diameter piston plate (4) with chamfered side of hole down. Cut cotton wicking (3) to required length and assemble against inner face of lip of leather packing; assemble expander ring (2) inside of felt with gripper points up and notch at loop end of expander ring under clip located near opposite end of expander ring; retainer plate (1) with cut-out portion over loop of expander ring; thread nut (9) onto push rod finger tight. Clamp hexagonal section of push rod in vise and securely tighten nut. Care must be taken to prevent retainer plate from shifting while tightening nut. Stake nut at two places.

Fig. 25 Disassembly of hydraulic cylinder end seal, hydraulic and vacuum push rod seals

Fig. 13. Place vacuum piston return spring over push rod with small end of spring next to vacuum piston and carefully guide push rod through leather seal in end plate. Use hook clamps illustrated to hold end plate and piston together. Wash hydraulic cylinder piston parts in alcohol and assemble parts as shown in inset. Dip hydraulic piston cup (1) in brake fluid before assembly. Lip of piston cup extends toward check valve end of piston. Attach hydraulic piston (5) to push rod by means of retainer pin (3). Slide snap ring (4) or pin retaining spring (2) over hole in piston to hold retainer pin in place.

Fig. 14. If the Hydrovac is of the type having a residual line pressure check valve, assemble check valve parts (2) into end cap (3) as illustrated in inset. Be sure lock ring (1) is in its groove. Place new gasket into end cap (7) and thread hydraulic cylinder (5) into end cap with milled flats next to end cap. Securely tighten. Assemble bleed screw (6) and thread lock nut (4) on cylinder to limit of threads.

Fig. 15. Place hydraulic cylinder end seal (2) in end plate against shoulder and guide lip of piston cup (1) into bore of cylinder (3). Thread cylinder in by hand until end of cylinder bottoms firmly against end seal. Do not tighten cylinder or lock nut at this time.

Fig. 16. Place gasket (1) on end plate. The rubber ring gasket furnished in the repair kit is for use with Hydrovacs having a gasket retaining groove in the end plate; if the end plate is not grooved, use Vellumoid gasket of the correct size. Dip piston leather in vacuum cylinder oil and allow excess to drain off. Coat inside of cylinder shell with vacuum cylinder oil. Insert piston into cylinder by tipping piston as shown. Line up end plate with scribed marks previously made before disassembly. Attach hook bolts and tighten each bolt evenly until all are uniformly tight.

Fig. 17. Place guide pins (2) in end plate as shown and carefully assemble control valve parts. Remove guide pins one at a time and replace with a screw and lock washer. When assembling diaphragm (5), return spring (6) and control valve body (7), extreme care should be taken not to distort the diaphragm in compressing the spring. Assemble vacuum hose (4) in place and tighten clamps. Tighten hydraulic cylinder to align bleed screw (8) in end cap with bleed screw (1) in end plate. Tighten lock nut (9) securely.

Tandem Piston Types

Disassembly

Fig. 18. Remove control valve cover and valve parts (1). Some Hydrovacs have a vacuum by-pass tube which must be removed before the valve housing can be taken off. The inset shows removal of control valve poppets.

Fig. 19. Force vacuum cylinder pistons forward by inserting the special return spring compressing tool (1) through opening in end plate. Attach flange (2) of tool to end plate, using three of the valve cover screws. (Details for making tool shown in Fig. 20.) Loosen hydraulic cylinder check nut and remove cylinder (8). Remove hydraulic piston (7) from push rod by sliding snap ring (6) or push rod pin retaining spring back on piston, then remove retainer pin (10). Hold end cap (9) in vise and remove hydraulic cylinder. Disassemble residual line pressure check valve parts (4). Loosen vacuum hose clamps (3) and slide both hoses toward center of vacuum tube. Remove hydraulic by-pass tube (opposite side of Hydrovac from that illustrated).

Fig. 21. Remove four cylinder studs (6) and disassemble end plates (1) and (4), cylinder shells (2) and (3), and center plate (5).

Fig. 22. Compress piston return spring by forcing center plate and vacuum piston (1) together. Insert rod (2) through hole in piston rod to hold spring compressed as shown. Place assembly ring (SER-434) over piston (5) and remove piston rod nut (7), push rod pin (3) and push rod (6). Lift off piston assembly, keeping piston parts assembled within the assembly ring. Remove piston rod nut (4), press down on center plate to remove rod (2). Then remove center plate and piston return spring from piston and piston rod (1).

Fig. 23. This operation and the one shown in Fig. 24 apply only to Hydrovacs having the fast application valve in the center plate. Remove fast application valve cover. Hold valve shaft (2) with screw driver in slot provided when loosening nut (1) and disassemble diaphragm parts.

Fig. 24. Continue on Hydrovacs having fast application valve in center plate as follows: Turn center plate over and

Fig. 26 Disassembly of hydraulic control valve fitting and piston

Fig. 27 Assembly of vacuum piston and piston rod

Fig. 28 Installing fast application valve and piston rod seals in center plate

Fig. 29 Assembly of fast application valve poppet and seat

Fig. 30 Assembly of fast application valve diaphragm and cover

Fig. 31 Assembly of rear vacuum piston, piston return spring and center plate

remove valve seat plate (1), gasket (2), poppet valve (3), and spring (4).

Fig. 25. On all models, place front end plate on bench, flat side down, and remove ring seal (1), snap ring (2), retainer washer (3), push rod seal spring (4), flange washer (5); push rod rubber cup seal (6), and guide washer (7). Drive out push rod leather seal (8).

Fig. 26. Place end plate over pins of holding fixture (inset). With holding fixture clamped in vise, remove retainer ring (1), using special tool T-25254, and remove stop washer (2). Using a 1⅞" socket wrench, remove hydraulic valve fitting (3), push out hydraulic piston (4), and remove piston cups (5). Remove gasket (6) from fitting.

NOTE—Clean all metal parts in Bendix Metalclene Parts Cleaner. Dip all metal parts used in hydraulic system in alcohol before assembly. Use all parts furnished in Hydrovac Repair Kit for the model being serviced. Discard old rubber parts. If bore of vacuum cylinder shell is corroded or rusted, polish with fine emery cloth or steel wool. If badly pitted or scored, the cylinder shell should be replaced.

Assembly

Fig. 27. If the rear vacuum piston has been disassembled to replace leather piston packing or other piston parts, reassemble piston as illustrated. Drill a 1⅜" hole in bench for piston rod. Thread nut (10) onto piston rod with flat side up. Drop piston rod (11) in hole of bench with by-pass hole end down. Assemble larger diameter piston plate (7) on piston rod with chamfered side of hole up. Guide rubber seal ring (5) over threads of piston rod. Place assembly ring (8) (SER-434) over piston plate and assemble piston parts as follows: Leather packing (6) with lip of packing up; smaller diameter piston plate (4) with chamfered side of hole down. Cut cotton wicking (3) to required length and assemble against inner face of lip of leather packing; assemble expander ring (2) inside of wick with gripper points up and notch at loop end of expander ring under clip located near opposite end of expander ring; retainer plate (1) with cut-out portion over loop of expander ring; thread nut (9) onto piston rod until flush with end of piston rod. Stake nut securely at two places. Clamp outer or staked nut in vise and securely tighten inner nut (10) against piston plate.

Fig. 28. Press leather seals (1) and (2) into place in center plate. Seal (1) should be flush with bottom of hole and seal (2) should rest against shoulder in center plate. On Hydrovacs without fast application valve seal (1) is not used and seal (2) should be pressed into center plate until flush with bottom of hole.

Fig. 29. Assemble fast application valve poppet into center plate. Be sure small end of return spring (4) is up. Place bullet nose tool (3) (T-25265) on poppet valve shaft at threaded end to prevent shoulder on valve shaft from damaging leather seal when assembling shaft. Install gasket, valve seat plate (1) with seat down and replace screws and lock washers.

Fig. 30. Turn center plate over and assemble diaphragm parts as illustrated, noting the following: Rounded edge of diaphragm plate (7) is up; place diaphragm gasket (6) on plate; assemble diaphragm (5) so that screw holes and by-pass hole lines up with holes in center plate (8); rounded edge of diaphragm plate (4) is down. Assemble nut (3), hold valve shaft with screw driver as nut (3) is tightened; stake nut at two places. Assemble cover gasket (2) and cover plate (1) with screws and lock washers.

Fig. 31. Place piston return spring (6) over piston rod with small end of spring next to piston. Carefully guide piston rod through leather seal in center plate (5), having piston stop flanges of

Fig. 32 Assembly of front vacuum piston and push rod

center plate up. Press down on center plate and insert rod (4) through hole in piston rod. Thread piston rod nut onto piston rod to limit of threads with flat side of nut up. If forward piston has been disassembled to replace leather piston packing or other parts, reassemble piston parts in assembly ring as shown in Fig. 27. Hold piston parts in assembly ring and turn assembly ring over. Remove outer or larger diameter piston plate (1) and seal ring (2). With assembly ring (3) still in place, guide remaining piston parts over end of piston rod up against piston nut. Carefully guide seal ring (2) over threads of piston rod and assemble larger diameter piston plate (1) over piston rod with chamfered side of hole down.

Fig. 32. Assemble large end of push rod (1) in end of piston rod and replace retainer pin (2). Thread piston rod nut (3) onto piston rod with flat side down until nut is flush with end of piston rod. Stake nut securely in two places. Hold piston rod nut (3) in vise or with wrench and tighten inner nut securely against piston. Care must be taken when tightening nut to prevent expander ring retainer plate from shifting. Remove assembly ring and then rod which was used to hold the return spring compressed during operations shown in Figs. 31 and 32.

Fig. 33. Hold end cap (4) in vise and assemble parts as shown. The small end of spring (2) must be placed inside clips of check valve (3). Hydraulic cylinder should be assembled with milled flats next to end cap. Thread lock nut up to limit of threads on hydraulic cylinder. Replace bleed screw in end cap.

Fig. 34. Press push rod leather seal (7) into front end plate (from side opposite to that shown). The lip of leather seal should be toward hydraulic cylinder end of end plate. Assemble push rod hydraulic seal parts as shown, noting the following: Chamfered side of stop washer (6) is down. Lip of cup (5) is up. Flat side of washer (4) is next to cup. Small end of spring (3) is down. Place washer (2) against spring. Install snap ring (1) into second (inner) groove of end plate.

Fig. 35. Assemble stop washer (2) with flat side into fitting (3) and retainer ring (1) using special tool T-25254. Dip piston cups (5) in brake fluid and assemble on piston (4) with lips of cups away from each other. Insert piston (4) into fitting (3) with hole end of piston next to stop washer (2). Place end plate on holding fixture. Use new copper gasket (6) on hydraulic fitting (3), without groove. Use new rubber seal gasket (6) on fitting (3) with groove. Securely tighten fitting into end plate with 1⅞" socket wrench. Where copper gasket (6) is used, fitting (3) should be tightened to approximately 4,000 inch-pounds of torque.

Fig. 36. Assemble poppet valves and related parts into control valve housing. Stake nut (1) at two places after assembly. If poppet valves are disassembled, always replace lead washer.

Fig. 37. Hold hydraulic cylinder end cap (2) in a vise and assemble parts. Thread hydraulic cylinder into front end plate—plate nearest to cylinder. Place gasket (1) on ledge of end plate, then place cylinder shell into position. Coat inside of cylinder shell with vacuum cylinder oil. Dip piston leathers in vacuum cylinder oil. Place gasket (3) on ledge of center plate. Guide push rod (4) carefully through seal in end plate. Align vacuum tube on center plate with vacuum tube on front end plate.

Fig. 38. Assemble rear cylinder shell and related parts. Assemble gasket (2)

Fig. 33 Assembly of residual pressure check valve, hydraulic cylinder and end cap

Fig. 34 Assembly of push rod seals, guide washer and piston stop washer

Fig. 35 Assembly of hydraulic control valve fitting and piston

Fig. 36 Assembly of vacuum control valve poppets

Fig. 37 Assembly of hydraulic cylinder, front end plate, front cylinder shell, center plate and pistons

Fig. 38 Assembly of rear cylinder shell, end plate and cylinder studs

Fig. 39 Assembly of hydraulic piston check valve and piston cup

Fig. 40 Assembly of hydraulic piston and cylinder assembly

on center plate. Coat inside of cylinder shell with vacuum cylinder oil. Tip cylinder shell to about 45° to prevent damage to leather packing and assemble in position. Place gasket (1) on ledge of rear end plate. Align and assemble end plate. Install cylinder studs and tighten evenly.

Fig. 39. Assemble hydraulic piston parts, noting the following: Large end of spring (3) goes in retainer cup (4). Lip of piston cup (1) extends toward check valve ball (2). Dip piston cup (1) in hydraulic fluid before assembling.

Fig. 40. Assemble vacuum hose (2) and hydraulic by-pass tube (on opposite side of Hydrovac from that shown). Remove hydraulic cylinder (5) and insert spring compressing tool (1). Attach flange of spring compressing tool with three screws. Assemble hydraulic piston (3) to push rod, being careful that lock ring or retaining spring is in position over retainer pin. Assemble hydraulic cylinder end seal (4) in groove of end plate.

Fig. 41. Thread hydraulic cylinder into end plate by hand until dimension "A" corresponds to the measurement given for the Hydrovac being serviced. For Atlas models the dimension is $7\frac{51}{64}$"; Mogul models $8\frac{51}{64}$"; Dreadnaught models $10\frac{5}{8}$"—all measurements to be correct within plus or minus ½ turn. Align bleed screw located in end cap with bleed screw located in control valve, holding dimension "A" to the nearest half-turn. Securely tighten lock nut. Remove spring compressor tool.

Fig. 42. Place guide pins (3) in end plate and carefully assemble parts. Remove guide pins one at a time and replace with a screw and lock washer. When assembling diaphragm (5), diaphragm gasket (4), return spring (2) and control valve body (1), extreme care should be taken not to distort the diaphragm in compressing the spring. Diaphragm stem (6) fits into hole of hydraulic control piston (7). If Hydrovac being repaired has a fast application valve, replace the fast application valve vacuum control tube.

Lubrication

Do not lubricate a Hydrovac until it is permanently installed on the vehicle. If lubricated beforehand, handling of the Hydrovac may cause oil to flow into the hydraulic portion of the unit and ruin the rubber parts. Have engine shut off and brakes released when adding vacuum cylinder oil.

All Model C single or tandem piston Hydrovacs should be lubricated on a mileage or time basis. Lubricate all 6¾" Model C Hydrovacs every 20,000 miles or once a year whichever occurs first; all 9½" single piston Hydrovacs every 10,000 miles or every six months whichever occurs first; all 9½" tandem piston Hydrovacs every 20,000 miles or once a year whichever occurs first. Early type Model C Hydrovacs do not have lubrication plugs.

To lubricate single piston Hydrovacs with lubrication plugs, remove lubrication plug and inject vacuum cylinder oil through the fitting up to the point where the oil begins to run out of the port—See Fig. 43. Replace and tighten plug.

To lubricate single piston Hydrovacs without lubrication plugs, loosen hose clamps and slide hose on tube connecting control valve with vacuum cylinder shell. On 6¾" diameter Hydrovacs slide hose toward control valve. On 9½" diameter Hydrovacs slide hose away from control valve end. Using gun type of oiler, inject specified quantity of vacuum cylinder oil into the Hydrovac through the control line tube. The spout of the oil gun should be inserted well down the bend of the tube to insure that all oil enters the vacuum cylinder—See Fig. 44. Use one ounce in all 6¾" and two ounces in all 9½" single piston type Hydrovacs.

To lubricate tandem piston type Hydrovacs with lubrication plugs, remove pipe plugs (1) and (2)—See Fig. 45, and inject vacuum cylinder oil through each port up to the point where the oil just begins to run out of the port. Replace pipe plugs and securely tighten.

To lubricate the forward piston of tandem piston Hydrovacs without lubrication plugs, remove the vacuum line tube elbow—See Fig. 46, and inject two ounces of vacuum cylinder oil into the front chamber, using care not to direct the oil onto the push rod. Replace tube elbow and reconnect vacuum line.

To lubricate the rear piston, remove the control valve housing—See Fig. 47, and inject two ounces of vacuum cylinder oil through the passage in the rear end plate. Replace the control valve housing.

Fig. 41 Cylinder stud to hydraulic cylinder end measurement

Fig. 42 Assembly of vacuum control valve diaphragm, valve housing and air cleaner cover

Air Cleaner Service

The air cleaner should be inspected every 1,000 miles and disassembled for cleaning. Where operating conditions are unusually dirty, perform this service more frequently.

Remove air cleaner cover screw, remove hair filter element and screens and wash in cleaning solvent. Dry, then saturate with light engine oil. Reassemble and install.

Air cleaner hose should be inspected for damage, and hose clamps secured to prevent leakage.

Vacuum Connections

Remove vacuum connection fitting from the intake manifold every 10,000 miles and inspect the elbow and vacuum line or tubing for possible obstruction. Also inspect hose fittings each 10,000 miles for tightness, and vacuum hose for damage or deterioration due to extreme conditions.

Bleeding Hydrovac, Manual

Manual bleeding requires filling the master cylinder reservoir and pumping the brake pedal to force the fluid through the lines to expel air from the system. This operation must be done with the engine shut off and no vacuum in the power brake system.

With the master cylinder reservoir filled, open No. 1 bleed screw on the Hydrovac (see Figs. 1 and 2) and depress the brake pedal to expel air. When the brake pedal has reached the toe board, close the bleed screw before returning pedal to release position. Repeat this procedure until solid fluid, free from

Fig. 43 Single piston with lubrication port

Fig. 44 Single piston without lubrication port

Fig. 45 Tandem piston with lubrication ports

Fig. 46 Tandem piston without lubrication ports (lubrication of forward piston)

Fig. 47 Tandem piston without lubrication ports (lubrication of rear piston)

bubbles, comes from the bleed screw. Check the master cylinder frequently to insure an ample supply of fluid.

Using this method, bleed No. 1 and No. 2 bleed screws on the Hydrovac and then proceed to the vehicle wheel cylinders.

Pressure Bleeding

This operation must be done with the engine shut off and no vacuum in the power brake system. Make certain there is sufficient brake fluid in the bleeder tank before starting and that the pressure is from 10 to 30 pounds per square inch.

With bleeder tank prepared, fill master cylinder reservoir before attaching hose from bleeder tank to the reservoir. With pressure from the bleeder tank applied to the master cylinder, bleed the Hydrovac first, starting with the bleed screw on the control valve (bleed screw No. 1). When a solid stream of fluid (free from bubbles) is obtained, close bleed screw securely and then bleed the Hydrovac hydraulic cylinder (bleed screw No. 2). Finally, proceed to the vehicle wheel cylinders and bleed them in like manner.

MODEL "C" DIAPHRAGM TYPE HYDROVAC

This device, Fig. 48, is a self-contained hydraulic-vacuum unit which consists of:

1. A vacuum power chamber which consists of a power diaphragm and a push rod that connects the power diaphragm to the hydraulic piston.
2. A hydraulic cylinder which contains a hydraulic piston and check valve.
3. A vacuum control valve which controls the power output of the vacuum power chamber in accordance to the hydraulic pressure developed within the brake master cylinder.

Disassembly

Use care in handling hydraulic system parts to prevent their coming into contact with mineral oil or greases. Do not handle hydraulic cups and seals with greasy hands.

Loosen check nut and unscrew hydraulic cylinder from end plate. Remove piston, cup and spring. Clamp end cap in vise to loosen hydraulic cylinder. Then remove check nut seal, check nut, hydraulic cylinder and gasket from end cap.

Scribe lines across two halves of diaphragm chamber and across end plate and control valve housing to assure correct reassembly.

Loosen hose clamps on control tube and slide hose toward control valve end. Remove end plate attaching nuts and lockwashers. Separate end plate assembly from vacuum power chamber and remove return spring. Remove snap ring, guide bearing, tube seal, push rod seal and stop washer from end plate.

Remove control valve housing and valve parts starting with lock ring. Remove control valve piston fitting lock ring and washer. With a socket wrench, remove fitting and press out piston. Re-

Fig. 48 Bendix Diaphragm Type Hydrovac

move cup from piston and seal ring from fitting.

Remove nut, lockwasher and bolt from clamp band and remove band. Remove diaphragm shell, diaphragm and push rod. Drive out attaching bolts and remove seals.

Clamp push rod nut in vise and remove nut, cupped washer, diaphragm, diaphragm plate and guide washer. If replacement of push rod is necessary, remove nut from push rod.

Cleaning

All parts that are to be reused should be thoroughly cleaned by immersion in an approved parts cleaner. After cleaning, those parts which come into contact with hydraulic brake fluid should be rewashed in clean alcohol before assembly. Use all parts furnished in the Hydrovac Repair Kit. Discard all old rubber parts.

Reassembly

Thread push rod nut onto push rod to limit of thread. Assemble guide washer; diaphragm plate with flat side next to diaphragm; diaphragm with cupped side next to diaphragm plate; large washer with concave side next to diaphragm and nut. Securely tighten nut and stake in place.

Install new rubber seals on bolts and assemble bolts in shell; stake bolts in shell. Place rear shell on bench and assemble diaphragm and push rod assembly and front shell. Align shells to scribe marks and bead on diaphragm with rim of shells. Assemble clamp band over rim of shells and assemble bolt, washer and nut. Securely tighten nut.

Dip piston cup in brake fluid and assemble on piston with lip of cup away from hole end of piston. Insert piston in fitting from threaded end with hole end of piston first. Place seal on fitting and screw fitting into end plate. Tighten fitting with a socket wrench. Install washer and lock ring in fitting (Truarc pliers No. T-25254 is recommended for this operation). Examine poppets in control valve; if damaged replace with Poppet Replacement Kit. Then assemble control valve parts as shown, noting the following: Stem of diaphragm goes into hole of valve piston; end of spring goes within rim of diaphragm flange; line up valve housing and end plate to scribe marks; small end of spring goes in recess of poppet.

Install new ring seal in groove of end plate flange. Place small end of return spring over guide washer of diaphragm. Align end plate and diaphragm chamber shells to scribe mark and attach end plate to diaphragm chamber, using washers and nuts. Tighten nuts securely. Slide control line hose over control tube and tighten hose clamps. Assemble stop washer over end of push rod (chamfered side first), push rod seal cap with flat side next to washer, hydraulic cylinder tube seal, push rod guide bearing with serrated end up. Press guide bearing down in end plate over push rod and assemble snap ring in groove of end plate.

Thread check nut onto hydraulic cylinder tube to limit of thread. Assemble check nut seal ring over thread against check nut and thread hydraulic cylinder tube into end plate (finger tight). Dip piston cup in brake fluid and assemble cup onto piston with lip of cup toward small diameter end of piston. Slide end of return spring over small end of piston and insert piston and spring in hydraulic cylinder. Install new gasket in end cap and thread end cap onto cylinder tube. Hold end cap in a vise and securely tighten cylinder tube into end cap, using open end wrench on flats of cylinder tube. Align outlet of end cap with bleed screw in control valve body and tighten check nut securely.

Fig. 49 MIDLAND vacuum booster with single diaphragm. This device allows the vehicle master cylinder to perform initial braking. After pressure in the system reaches 40 lbs., air is admitted to the power chamber and the diaphragm forces the slave cylinder forward to boost the pressure to wheel cylinders

MIDLAND BRAKE BOOSTER

Fig. 49—The vacuum chamber is divided into two halves which are held together by a clamping ring. The outer edge of the diaphragm is clamped between the two halves of the chamber. A push rod is fastened to the diaphragm and extends into the slave cylinder and butts against the slave cylinder piston.

The vacuum control valve is actuated by hydraulic pressure from the brake master cylinder piston.

The slave cylinder is somewhat similar to the brake master cylinder in that it contains a piston, piston cup and a spring to force the piston back when the brakes are released. The piston is made in two parts, one inside the other. A coil spring inside the outer half tends to force the two halves apart, the inner half being prevented from coming entirely out of the outer half by a snap ring.

When it is desired to use the tractor brake pedal to operate both the tractor and trailer brakes, a synchronizing valve should be used to control the trailer brakes. This valve properly synchronizes the tractor and trailer brakes. If it is not used, the tractor brakes will not only start to brake before the trailer but also most of the braking will be done by the tractor brakes.

The valve is not necessary when a hand control is used to control the trailer brakes.

Operation

A tube from the engine intake extends to a check valve and then to the front side of the vacuum chamber so that vacuum is present on the slave cylinder side of the vacuum chamber diaphragm at all times that the engine is running.

Fig. 50 Bendix "Air-Pak" Power Unit

A tube from the rear side of the vacuum chamber extends to the vacuum control valve and, when the brakes are not applied, there is an open passage through the control valve to the front side of the chamber. Thus, when the brakes are not applied, the two sides of the chamber are directly connected and there is vacuum present on each side of the diaphragm.

A brake tube extends from the regular master cylinder to the vacuum control valve. When the brakes are applied, brake fluid is forced through a passage in the control valve to a space under the control valve diaphragm piston. The pressure then moves the piston against the air intake valve, closing the vacuum passage and opening up an air passage to the rear side of the vacuum chamber.

The difference in pressure on each side of the chamber diaphragm—vacuum on one side and air on the other—forces it toward the slave cylinder.

At the time the brakes are first applied, brake fluid is forced through passages in the control valve and slave cylinder into the space between the two halves of the slave cylinder piston and through a hole in the piston into the slave cylinder and brake lines to the wheel brake cylinders.

As the chamber diaphragm push rod moves into the slave cylinder, it presses the inner half of the piston into the outer half, closing the hole in the piston and trapping the brake fluid in the slave cylinder and brake lines. Then as the chamber diaphragm push rod continues to move the piston, the brakes are applied.

If at any time the booster does not function when the brake pedal is depressed, the brake fluid will simply pass through the hole in the slave cylinder piston and pressure can be applied through the master cylinder the same as if there was no booster on the vehicle.

When the brake pedal is released, a spring forces the vacuum control piston back, closing the air passage and opening the vacuum passage to the rear side of the vacuum chamber. The diaphragm is pushed to the rear end of the chamber by a spring, thus relieving pressure on the slave cylinder piston and releasing the brakes.

Testing for Leakage

1. Depress brake pedal with full pressure and, while holding the pedal in this position, start the engine. The pedal should then move downward. If not, disconnect the manifold-to-booster chamber tube at the booster. Insert a vacuum gauge and reconnect the tube. Start the engine and check the vacuum—which should be 18 to 21 inches. If normal, the difficulty is located in the booster unit.
2. Remove the pipe plug from the rear half of the booster chamber and install a vacuum gauge.
3. With engine running, depress brake pedal with sufficient pressure to show a zero reading on the vacuum gauge. Shut off the engine and hold the pedal in this position for one minute. A kickback of the pedal indicates a vacuum leak. Do not attempt to locate the leak until step No. 4 has been completed.
4. Start the engine to create vacuum in the system. Then stop the engine and observe the vacuum gauge—the drop in vacuum should not be more than one inch per minute. If more than this, a vacuum leak is present.

Leakage in test No. 3 but not in No. 4 indicates that the booster unit itself is at fault. Leakage in tests 3 and 4 may be located in the check valve on dash, vacuum tube connections, or booster unit itself.

Disassembly

1. Remove large nut at end of slave cylinder and remove piston spring and metal cup.
2. Scratch mark both halves of vacuum chamber so that they can be assembled together in their original position.
3. Punch mark flanges of control valve and slave cylinder (marks opposite each other) so that they can be assembled together in their original position.
4. Remove control valve-to-vacuum chamber tube.
5. Remove ring which clamps two halves of vacuum chamber together and remove rear half of vacuum chamber and diaphragm.
6. Remove screws which fasten front half of vacuum chamber to slave cylinder. Remove seal retainer and front half of vacuum chamber.
7. Remove screws holding valve cover to control valve and take off cover. Lift out valve spring and air valve.
8. Remove control valve. Lift off diaphragm spring and diaphragm.
9. Remove rubber piston seal from rear end of slave cylinder.
10. Using the vacuum chamber diaphragm push rod, push slave cylinder piston and rubber piston cup out of front end of cylinder.

Reassembly

Reverse the order of the disassembly procedure to reassemble, being sure to line up the two halves of the vacuum chamber as well as the control valve and slave cylinder according to the marks made prior to disassembly.

The control valve diaphragm and vacuum chamber diaphragm can be installed in any position.

BENDIX AIR-PAK POWER UNIT

The Bendix Air-Pak is a combination compressed air, hydraulic power brake unit for use on vehicles having hydraulic brakes and a source of compressed air for brake operation. The device consists of three basic units, Fig. 50.

1. A compressed air cylinder, which includes an air pressure-operated piston and a push rod.
2. A hydraulic cylinder, which includes a hydraulic piston with a built-in check and a residual check valve at the output end of the cylinder.
3. An air pressure control valve, which includes a hydraulic pressure-operated piston, an air pressure poppet valve, an atmospheric pressure pop-

pet valve, and an air pressure control diaphragm.

Principles of Operation

As the brake pedal is depressed, fluid is displaced under pressure by the master cylinder piston to the hydraulic cylinder and to the hydraulic piston chamber of the control valve of the "Air-Pak". When sufficient pressure develops, the hydraulic piston of the control valve moves, closing off the atmospheric poppet valve and opening the air pressure valve to admit air under pressure to the air pressure side of the "Air-Pak" air cylinder.

The air pressure, acting upon the air cylinder piston, is transmitted through the push rod to the hydraulic cylinder piston, moving the piston in the applied direction. As soon as the piston begins to move, the check valve in the hydraulic piston closes to prevent the return of fluid to the master cylinder.

Any increase in fluid pressure or piston travel is transmitted to the wheel cylinder pistons to actuate the brakes. The hydraulic pressure at the wheel cylinder piston is the sum of the pressure developed by the air power cylinder piston.

A diaphragm in the control valve, which is subject to atmospheric and application air pressure, controls the degree of braking by setting up an opposing force which resists the movement of the control valve hydraulic piston in the applied direction.

With the release of pressure applied to the brake pedal, the hydraulic pressure within the master cylinder and control valve piston cavity decreases, causing the air pressure poppet to close and the atmospheric poppet to reopen. As the atmospheric poppet opens, the pressure on both sides of the air cylinder pistons are again balanced. The return spring then returns the air cylinder and hydraulic cylinder pistons to their released positions.

As the hydraulic cylinder piston approaches its fully released position, the check valve in the hydraulic piston reopens to permit the fluid displaced by the hydraulic piston of the "Air-Pak" to return to the master cylinder, releasing the brakes.

Disassembly

Use extreme care in handling hydraulic system parts to prevent their coming in contact with mineral oil or greases. Do not handle hydraulic piston cups or seals with greasy hands.

1. Loosen control tube nuts and remove control tube and gasket.
2. Scribe marks across end plate and cylinder shell and also across end plate and control valve housing to assure correct reassembly.
3. Remove end plug, gasket and spring from control valve housing. Then remove six capscrews, lift or pry off housing and remove return spring, diaphragm assembly and stop washer.
4. Clamp nut in vise and with a drift inserted through hole in adapter, remove adapter, diaphragm and washer.
5. Clamp end cap firmly in vise and loosen check nut. Then remove six nuts, washers and bolts and the short bolts.
6. Tap cylinder shell with soft hammer to break bond between end plate and cylinder shell and remove shell and air piston.
7. Clamp nut of air piston in vise. Place end of push rod in hole of piston and compress return spring sufficient to assemble hook clamps (5⅜" long) over piston and end plate.
8. With spring held compressed, remove hydraulic cylinder assembly from end plate.
9. Compress retainer spring on piston, remove retainer pin and hydraulic piston from push rod.
10. Press down on end plate, remove hook clamps, end plate, spring and push rod. Then remove piston from vise.
11. To disassemble piston, remove snap ring, retainer cup, spring, ball and then remove piston cup from piston.
12. Clamp end cap rigidly in vise and loosen hydraulic cylinder tube with an open end wrench. Then remove check nut seal, check nut, hydraulic cylinder tube and copper gasket.
13. To dismantle the residual check valve, remove snap ring, stop washer, return spring, residual check valve and bleed screw.
14. Loosen control valve piston fitting with a suitable offset wrench. Then remove lock ring, fitting and gasket.
15. Remove hydraulic tube seal, snap ring, stop washer, seal retainer, push rod cup and stop washer.
16. Remove push rod leather seal and gasket.
17. To remove seal, thread a ¼" pipe top into seal and drive seal out from opposite end.
18. Press out control valve piston from fitting and remove cups from piston.

Cleaning & Inspection

Clean all metal parts except the control valve housing and poppets in an approved parts cleaner. After cleaning, wash all hydraulic system parts in clean alcohol before assembly. When overhauling an "Air-Pak", always use a repair kit.

Inspect all parts for excessive wear or damage. If the bore of the air cylinder shell is corroded or rusted, polish with fine emery cloth or steel wool. When cylinder shell is badly scored or pitted, it should be replaced.

Inspect the condition of poppets and seat in control valve housing. If either are damaged, replace the control valve housing and poppets assembly.

Reassembly

1. Assemble new rubber gasket and leather seal in end plate. Lip of leather goes next to gasket.
2. Assemble stop washer with chamfered side next to seal; push-rod cup, with flat side next to stop washer; seal retainer with counterboard side next to cup; stop washer; snap ring and rubber seal.
3. Wash control valve piston cups, fitting and piston in clean alcohol and then dip cups in brake fluid. Then assemble cups on piston. **NOTE**—Cut with red dot goes on hole end of piston.
4. Insert piston and cups in fitting from end opposite lock ring groove. Use new gasket on fitting and securely tighten fitting into end plate. Replace lock ring in fitting.
5. Assemble residual check valve in end cap. Place new copper gasket in end cap and then thread hydraulic cylinder tube into end cap with milled flats on tube next to end cap.
6. With end cap held firmly in vise, securely tighten cylinder tube into end cap.
7. Assemble check nut and seal on cylinder tube and turn nut down to end of threads.
8. Dip hydraulic piston cup in brake fluid and assemble cup into piston with lip of cup toward check valve.
9. Clamp air piston nut firmly in vise and insert lock ring end of push rod in hole of piston.
10. Assemble retaining washer on push rod with cup side up and assemble return spring with small diameter end next to retainer washer.
11. Guide end plate over push rod, compress return spring and hold spring compressed with the hook clamps used for disassembly.
12. Compress retainer pin spring on piston and attach piston to push rod with retainer pin. Make certain pin is held in position by spring.
13. Carefully guide hydraulic cylinder over lip of piston cup and thread cylinder into end plate (hand tight only).
14. Compress return spring and remove hook clamps.
15. Saturate air piston leather and cotton wicking in Bendix Vacuum Cylinder oil. Allow excess oil to drain off. Also apply a light coating of oil to inside of cylinder shell.
16. Install new end plate gasket in groove of end plate. Place piston on end of push rod.
17. Assemble air cylinder over piston and align to scribe marks. Attach air cylinder to end plate. Tighten each bolt evenly until all bolts are uniformly tight.
18. With check nut loose, adjust length of hydraulic cylinder to the following dimensions, measuring from extreme end of end cap to end plate:

Part No.	Dimension*
375440	7½"
375756	7½"
375757	10¼"
375817	7½"
375844	10¼"
375901	7½"

*Plus or minus ⅛".

19. Assemble nut, washer, diaphragm and adapter (flat side of washer goes next to nut, concave side of diaphragm goes next to washer). Hold nut in vise and securely tighten adapter.
20. Thread two guide pins into end plate (make from ¼-20 screw, 2½" long). Place stop washer in recess of end plate (flat side out) and assemble diaphragm, return spring and control valve housing, with housing aligned to scribe marks.
21. Assemble capscrews and lockwashers. Tighten screws uniformly.
22. Place new gasket on fitting. Assemble small end of spring over end of air poppet and thread fitting into end plate and tighten fitting.
23. Place new gasket on air control tube and attach tube to control valve and air cylinder, securely tightening nuts.

Lubrication

Do not lubricate "Air-Pak" until it has been permanently installed on the vehicle. This is a safeguard against lubricating oil entering the hydraulic section of the "Air-Pak" which might cause damage to the rubber cups and seals.

The "Air-Pak" should be lubricated every 10,000 miles or every six months, whichever occurs first, with Bendix Vacuum cylinder oil.

To lubricate the "Air-Pak", remove the ⅛" pipe plug from the air cylinder shell and inject the oil through the fitting up to the point where the oil begins to run out of the port. Replace and tighten the plug.

During lubrication, the engine should be shut off and the "Air-Pak" should be in the released position.

POWER BRAKE TROUBLE DIAGNOSIS

Hard Pedal

1. Vacuum failure due to faulty vacuum check valve, collapsed vacuum hose, or plugged vacuum fittings.
2. Bound-up pedal shaft.
3. Glazed linings.
4. Grease on linings.
5. Power cylinder troubles.

Grabby Brakes

1. Grease on linings.
2. Scored brake drums.
3. Anchor pins bound-up.
4. Power cylinder valve trouble.

Pedal Goes to Floor

1. Brakes need adjustment.
2. Air in hydraulic system.
3. Hydraulic leak.
4. Low master cylinder fluid level.
5. Cracked brake drum.
6. Power cylinder leakage.

Brakes Fail to Release

1. Master cylinder compensating port covered or plugged.
2. Anchor pins bound-up.
3. Bound-up brake pedal shaft.
4. Faulty hydraulic check valve (at master or power cylinder).
5. Brakes improperly adjusted.
6. Power cylinder valve or ball check trouble.

DESCRIPTION

This transmission, Fig. 1, called Powermatic by Chevrolet and Transmatic Drive by Ford, and Torqmatic by Dodge, is a hydraulically-operated automatic transmission with six forward gear ratios and one reverse ratio. It is made in two versions, a lighter unit for medium duty trucks and a heavier one for heavy duty trucks. The two models differ chiefly in the hydraulic control system.

The transmission consists basically of a torque converter, a planetary gear train and a hydraulic control system for shifting gears.

The torque converter operates as a hydraulic torque multiplier and a fluid coupling between the truck's engine and the gear train. The torque multiplying phase of the converter operates when the truck starts moving from a standstill and when a heavy load slows down the truck. When no torque multiplication is needed, the fluid coupling phase starts operating automatically.

If the truck should slow down and the converter turbine resists turning, such as when climbing hills or driving in stop-and-go traffic, the converter operation automatically changes from a fluid coupling phase to a torque multiplication phase. This phase occurs after the gears have shifted into third gear ratio (when driving in Drive or Intermediate ranges) or first gear ratio (when in Low range).

At certain engine speeds when the action of the torque converter is no longer needed, an automatic lockup clutch in the converter locks the engine directly to the gear train for greater efficiency, Fig. 2. The hydraulic system which operates the lockup clutch automatically disengages the clutch each time an automatic or manual upshift or downshift is being made.

A pedal-operated hydraulic retarder in the transmission assists the service brakes in controlling the truck's speed during long downhill braking or when slowing down in stop-and-go traffic. When the retarder pedal is depressed and the retarder valve opens, transmission fluid flows into the retarder cavity located between the converter and transmission housings. The cavity contains a rotor, which is connected to the turbine output shaft, and stationary reaction vanes on both sides of the rotor. When the fluid fills the cavity, it churns against the reaction vanes and slows down the rotor. The retarding effort is transmitted to the drive line and slows down the truck.

The retarder will continue to operate as long as the retarder pedal is depressed. However, heat is generated in the fluid by the retarder action, and the fluid

Fig. 1 Sectional view of Allison six-speed automatic transmission

temperature may rise faster than it can be cooled if the retarder is operated continuously. A warning light on the instrument panel indicates that the retarder operation should be discontinued until the fluid cools and the warning light goes out. When the pedal is released and the retarder valve closes, the fluid in the cavity automatically discharges and permits the rotor to turn without drag.

The transmission gear train contains four sets of constant-mesh planetary gears which are operated by hydraulically-actuated clutches. All forward gear shifts, except the upshift and downshift between second and third gear ratios, are fully automatic and are controlled, through a system of hydraulic valves, by throttle position and truck speed.

The four planetaries are arranged in series to permit one of them to become a "splitter" for the others. The splitter planetary, located between the torque converter and the range gears, has two ratios that are used when the low, intermediate or high clutch is applied. A reduction ratio, or low splitter, operates in neutral, first, third, fifth and reverse gears. A direct drive ratio, or high splitter, is used in second, fourth and sixth gears.

Two separate fluid-velocity governors in the transmission provide the fluid pressures needed to operate the hydraulic control system and make the shifts.

Two regular duty power take-off openings are located at the sides of the transmission housing.

DRIVING INSTRUCTIONS

The manual controls needed to operate the transmission are a range selector lever, an accelerator pedal, and a pedal for the hydraulic retarder.

A neutral position (N), three forward speed positions (Dr, Int and Lo) are provided for the range selector lever to control the various automatic gear ratio shifts in the transmission.

The selector lever must be at N to start the engine. When the lever is at Dr, the transmission can be operated in 3rd, 4th, 5th and 6th gear ratios. The Int (intermediate range) position permits the use of only 3rd and 4th gear ratios. When the lever is in Lo (low range) the transmission will operate only in 1st and 2nd gear ratios. The reverse gear ratio can be used when the selector lever is at R.

When the truck is moving forward, the selector lever can be moved from one forward speed to another to obtain gear ratios in the other ranges. However, the lever should not be moved from Dr to Int when the truck is moving faster than 30 mph, or from Dr or Int to Lo at speeds faster than 15 mph. *Do not move the lever between ranges when the hydraulic retarder is operating. The truck should always be completely stopped when shifting the selector lever from Dr, Int or Lo to R. Severe damage to the transmission may result from shifting the selector lever at road speeds faster than those specified for the shifts.*

The gear ratios within the selected range are upshifted or downshifted automatically to meet changing road and load conditions. When the accelerator is depressed to provide maximum or full throttle, each gear ratio shift point should occur at the highest speed for the shift. When the throttle is partly open, the shift points should occur at lower speeds.

A detent at full-throttle position of

Fig. 2 Lockup clutch

the accelerator pedal permits the driver to control certain shifts. When the pedal is pushed through the full-throttle detent, the transmission will remain in the same gear ratio during acceleration or will immediately downshift to a lower gear ratio to provide the best engine performance for the driving conditions. The transmission cannot upshift when the accelerator is pushed through the full-throttle detent. The pedal must be released until it comes back through the full-throttle detent to obtain an upshift.

Driving On Glare Ice

To start the truck moving from a standstill on glare ice when traction is poor, place the selector lever at Dr or Int and depress the accelerator pedal as lightly as possible to avoid spinning the wheels. *Do not downshift to Lo.*

"Rocking" Out of Deep Ruts

To "rock" the truck out of deep ruts, move the selector lever back and forth between Lo and R while keeping the engine running at a steady speed. Time the movement of the lever to take advantage of the "rocking" momentum of the truck.

Pushing or Towing To Start The Engine

If the truck has to be pushed or towed to start the engine, place the selector lever at N and turn on the ignition switch. When the truck's speed reaches about 25 mph, move the selector lever to Dr and hold the accelerator pedal about halfway down. If the truck is being towed, be careful not to run into the towing truck when the engine starts.

Towing The Truck

To tow a truck when the transmission is not functioning properly, raise the rear wheels off the ground or disconnect the drive shaft.

When the transmission is functioning properly but has not been driven more than 1000 miles, or when mechanical trouble exists elsewhere in the truck, place the selector lever at N and maintain a towing speed between 15 and 35 mph. Check the transmission fluid level after each three miles of towing, and add fluid if the level falls more than ¼" below the full mark.

Operating The Hydraulic Retarder

The hydraulic retarder is not a substitute for the service brakes but is designed only to slow down the truck. It assists the brakes and relieves them from excessive use and wear during long downhill braking and when slowing down in stop-and-go traffic.

To slow down the truck, push down and hold the hydraulic retarder pedal. The retarder operates most effectively in the intermediate and low ranges at engine speeds of 2800-3500 rpm.

Trouble Shooting & Maintenance

TROUBLE SHOOTING

Shift Points High on 1st and 2nd and all Lockup Shifts

1. G-1 Pressure insufficient.
2. Lube pressure low.
3. Anchor bolts holding diaphragm in housing loose.
4. G-1 circuit leakage.
5. Front fluid velocity governor damaged.
6. Front pitot tube loose or damaged.

Lockup Shift Points High and Transmission Won't Shift to 2nd Gear

1. G-1 pressure insufficient.
2. Lube pressure low.
3. G-1 circuit leakage.
4. Lockup shift valve sticking.
5. Anchor bolts holding high range clutch diaphragm in housing loose.
6. Front fluid velocity governor damaged.
7. Front pitot tube loose or damaged.

Low-Main Pressure In All Ranges

1. Air leak at oil transfer tubes or seals in oil pan.
2. Oil filter element clogged.
3. Main pressure regulator valve primary and secondary springs weak or improper.
4. TV pressure low at full throttle; normal at closed throttle.
5. TV spring weak or broken.
6. Range selector valve body leakage.
7. Oil transfer plate gasket blown or damaged.
8. Rear pump ball not in range selector valve body.
9. Valves sticking.
10. Front pump worn or damaged.

Low Main Pressure In Low Range

1. Low range circuit of range selector valve body leaking.
2. Leakage between low range piston housing and transmission housing.
3. Excessive leakage at low range piston seals.
4. Gasket at oil transfer plate leaking.

Misses 2nd Gear On Downshift to Low Range

1. Shifting manually at too low vehicle speed.
2. G-1 pressure insufficient.
3. Rear oil pump malfunctioning.

Transmission Will Not Shift to 4th Gear In Int or Dr Ranges

1. G-2 pressure insufficient.
2. Rear pitot tube loose.
3. Rear pitot (G-2) splitter plug sticking.
4. Rear fluid velocity governor damaged.
5. Rear oil pump malfunction or orifice in pump housing clogged.
6. Rear pitot tube damaged or improperly installed.

All Shift Points Too Low At Full Throttle

1. TV pressure low at full throttle.
2. Throttle valve spring weak or broken.
3. Main pressure leaking into governor circuit.

All Shift Points Too High Except Lockup and 1st and 2nd Shift At Part Throttle

1. G-2 pressure insufficient.
2. Rear pitot tube loose.
3. Rear fluid velocity governor damaged.
4. Rear pitot tube damaged.

Buzzing Noise Occurring Intermittently

1. Low oil level.
2. Oil filter element clogged.
3. Air leak at oil transfer tubes or seals in oil pan.

Insufficient G-2 Pressure

1. Rear pitot tube loose.
2. Rear fluid velocity governor damaged.
3. Rear pitot tube damaged or improperly installed.
4. Rear oil pump malfunction.
5. Oil transfer plate gasket blown or damaged.

Insufficient G-1 Pressure

1. Lube pressure low.
2. G-1 circuit leak or obstruction.
3. Anchor bolts holding high range clutch diaphragm in housing loose.
4. Front fluid velocity governor damaged.
5. Front pitot tube damaged or loose.

Low Lube Pressure

1. Oil lines restricted.
2. Cooler lines or fittings leaking.
3. Lube regulator valve ball or spring in hydraulic retarder control valve body faulty.
4. Oil filter element clogged.
5. Pump overage regulator malfunction.
6. Front oil pump malfunction.
7. Converter pressure regulator valve ball malfunction.
8. Oil level low.

Oil Leakage Into Converter Housing

1. Engine crankshaft rear oil seal leaking.
2. Torque converter seals leaking.
3. Front oil pump lip-type seal faulty or seal drain restricted.
4. Hook-type seal ring on converter pump hub broken.
5. Drive studs in converter pump cover loose.
6. O-type seal ring at front oil pump leaking.

Transmission Heating Up In All Ranges

1. Oil level low.
2. Oil level high.
3. Engine cooling system malfunction.
4. Oil cooler lines restricted.
5. Hydraulic retarder partially applied.
6. Bushing in converter ground sleeve worn.

Lockup Clutch Will Not Engage

1. G-1 pressure insufficient.
2. Lockup shift valve or lockup cutoff valve sticking.
3. Hook-type seal rings on splitter shaft or turbine shaft broken.
4. Lockup clutch piston seal ring leaking.
5. Excessive internal leakage.

No Response to Movement of Shift Lever

1. Oil filter clogged.
2. Oil level low.
3. Range selector linkage defective.
4. Main pressure low.
5. Low splitter clutch failure.
6. Clutch piston seals leaking.

High Stall Speed

1. Oil level low.
2. Clutch pressure low.
3. Converter pressure low.
4. Range clutches failure.
5. Low splitter clutch failure.

Low Stall Speed

1. Engine not performing efficiently.
2. Converter stators functioning improperly due to improper assembly or failure of components.

Rough Shifting

1. Manual selector linkage out of adjustment.
2. Throttle valve linkage out of adjustment.
3. Valves sticking.

Engine Overspeeds On Full Throttle Shift Out of Low Range

1. Downshift timing valve sticking.
2. Seals on intermediate range clutch piston excessively worn.

Loss of Hydraulic Retarder Braking Effect

1. Oil level low.
2. Hydraulic retarder valve linkage out of adjustment.
3. Oil filter element clogged.
4. Air leaks at oil transfer tubes or seals in oil pan.
5. Lube regulator valve in hydraulic retarder valve body failure.
6. Hook-type seal ring on outside diameter of splitter ring gear faulty.

Excessive Slippage and Clutch Chatter In 1st and 2nd Lockup Only

1. Low range clutch failure.
2. Excessive leakage of low range clutch piston seals.

Excessive Slippage and Clutch Chatter In 1st, 3rd and 5th Gear Lockup Only

1. Low splitter clutch failure.
2. Anchor bolts holding high range clutch diaphragm in housing loose.
3. Excessive leaking of low splitter clutch piston seals.

Excessive Slippage and Clutch Chatter in 2nd, 4th and 6th Gear

1. High splitter clutch slipping.
2. Anchor bolts holding high range clutch diaphragm in housing loose.
3. Excessive leaking of high splitter clutch piston seals.

Excessive Slippage In 3rd and 4th Gear Lockup Only

1. Intermediate range clutch failure.
2. Intermediate range clutch piston seals leaking excessively.

Dirty Oil

1. Failure to change at specified interval.
2. Oil filter element faulty.
3. Excessive heat.
4. Clutch failure.

Slippage In 5th and 6th Gear Lockup Only

1. High range clutch slippage.
2. High range clutch piston seals leaking excessively.

Slippage In All Gears

1. Oil level low.
2. Clutch pressure low.
3. Lockup clutch slipping.

Excessive Slippage In Reverse Range Lockup Only

1. Reverse range clutch failure.
2. Reverse range clutch piston seals leaking excessively.

Vehicle Moves Forward In Neutral

1. Range selector linkage out of adjustment.
2. Range clutch failure or dragging.

3. Insufficient range clutch clearances.

Vehicle Moves Backward In Neutral

1. Range selector linkage out of adjustment.
2. Reverse range clutch failure or dragging.

Vehicle Will Not Push Start

1. Engine trouble.
2. Oil level low.
3. Rear oil pump malfunction.
4. Also refer to troubles concerning excessive clutch slippage and failure of vehicle to move when engine is running and selector is shifted to forward ranges.

Throws Oil Out of Transmission Filler Tube

1. Dipstick loose.
2. Breather line clogged, disconnected or pinched.
3. Oil level too high.

Oil Leak At Rear Bearing Retainer

1. Bearing retainer bolts loose.
2. Retainer gasket blown.
3. Gasket of improper thickness installed.

OIL PRESSURE CHECKS

Plugged holes are provided for checking oil pressures, Fig. 3. These plugs can be removed for the installation of oil pressure gauges.

CAUTION—*Do not install any gauges while the engine is running. By using these oil pressure check points, abnormal oil pressures that will cause malfunction of the hydraulic-controlled components can be found. The following data applies to the medium duty unit. Full throttle pressures for the heavy duty unit are 10% higher.*

Gear	*Operation*	*P.S.I.**
1st	Converter	
	closed throttle	185
	full throttle	220
	Lockup	
	closed throttle	70
	full throttle	82
2nd	Lockup	
	closed throttle	70
	full throttle	82
3rd	Converter	
	closed throttle	185
	full throttle	220
	Lockup	
	closed throttle	85
	full throttle	100
4th	Lockup	
	closed throttle	70
	full throttle	82
5th	Lockup	
	closed throttle	70
	full throttle	82
6th	Lockup	
	closed throttle	70
	full throttle	82
Reverse	Converter	
	closed throttle	185
	full throttle	220
	Lockup	
	closed throttle	70
	full throttle	82

*The above data are for medium duty units; full throttle operation on heavy duty units are 10% higher.

AIR PRESSURE CHECKS

Compressed air may be used to check the operation of the various clutches in the transmission and to find leaks that may be caused by broken, damaged or omitted seals.

To make the air pressure checks, remove the oil pan, valve body and oil transfer plate from the transmission. Then apply 80-100 lbs. (psi) air pressure at the appropriate holes in the mounting pad at the bottom of the transmission housing, Figs. 3 and 4.

When compressed air is applied as directed, listen for the noise that occurs when the clutch is applied. If no clutch application noise is heard, a leak may exist in the hydraulic system. Refer to the fluid leakage data below to determine the cause of the leaks at any of the check points.

Low Splitter Clutch

1. Leak between diaphragm and case:—Bottom two anchor bolts loose or not drawing diaphragm to case.

High Splitter Clutch

1. Leak between diaphragm and case:—Bottom two anchor bolts loose or not drawing diaphragm to case.
2. Leak at piston I.D.: — Broken or omitted hook-type oil seal.
3. Leak at piston O.D.: — Broken, nicked or omitted synthetic seal.
4. Air comes out of lube hole in retarder valve body pad:—Front hub hook-type seal ring broken or omitted.
5. Air comes out of retarder feed:—Rear hub hook-type seal ring broken or omitted.

High Range Clutch

1. Leak between diaphragm and case:—Bottom two anchor bolts loose or not drawing diaphragm to case.
2. Air escapes at front pitot hole (8) or at lube hole in retarder valve body pad:—Inner hook-type seal ring on rear hub broken or omitted.
3. Air escapes at lube hole in retarder valve body pad:—Rear hook-type seal ring on rear hub broken or omitted.
4. Air may escape around clutch piston spring:—Hook-type seal ring for clutch I.D. broken or omitted.
5. Air may escape around high range clutch hub:—Synthetic seal at piston O.D. broken, nicked or omitted.

Intermediate Range Clutch

1. Leak between case and intermediate clutch piston housing:—Anchor bolts loose. Intermediate clutch housing not tight against hole in case.
2. Leak at piston I.D.: — Hook-type ring broken or omitted.
3. Air escapes around low range clutch plate:—Hook-type ring broken or omitted.
4. Leak at piston O.D.:—Synthetic seal at piston O.D. broken, nicked or omitted.

Low Range Clutch

1. Leak between case and low-reverse piston housing:—Anchor bolt loose. Low-reverse clutch housing not tight against case.
2. Leak at piston I.D.:—Hook-type seal broken or omitted.
3. Air escapes around clutch I.D.:—Hook-type seal broken or omitted.
4. Leak at piston O.D.:—Synthetic seal broken, nicked or omitted.

Reverse Clutch

1. Leak between case and low-reverse

Fig. 3 Pressure check point locations

piston housing:—Anchor bolt loose. Low-reverse clutch housing not tight against case.
2. Leak at piston I.D.:—Hook-type seal broken or omitted.
3. Air escapes around clutch I.D.:—Hook-type seal broken or omitted.
4. Leak at piston O.D.:—Synthetic seal broken, nicked or omitted.

Lockup Clutch

1. Leak at piston I.D.:—Synthetic seal broken, nicked or omitted.
2. Leak at O.D. of converter cover:—Synthetic seal between reaction plate and cover, or between plate and converter pump flange damaged or omitted.
3. Leak at turbine shaft:—Broken or omitted hook-type rings at front end of turbine shaft, front end of splitter shaft, or center of splitter shaft.

MAINTENANCE

Adding Fluid

The oil level should be checked every 1000 miles and oil added as necessary as outlined below:

1. Transmission oil should be at normal operating temperature of 150 to 200°.
2. Apply hand brake and service brakes securely. *Do not apply the hydraulic retarder while checking the oil level.* Applying the hydraulic retarder while in a stalled condition will aerate the oil, making an accurate oil level check impossible.
3. Place range selector lever in Dr range and run engine at normal idle speed.
4. Before removing dipstick clean the area around the dipstick opening as a precaution against dirt entering transmission.
5. The oil level should be at the "Full" mark on the dipstick. If the oil level it at the "Add" mark, or below it, add enough oil to bring the level up to the "Full" mark. If the oil level is higher than the level specified above, drain the oil back to the correct level.
6. Securely seat the dipstick in the filler tube.

Changing Fluid

The oil should be changed every 5000 miles under normal operating conditions for off-highway or urban operation. The oil should be changed at 10,000 mile intervals for normal highway operation. Replace the oil filter at each change.

Fig. 4 Transmission housing fluid passage holes

1. Drain oil immediately after operation while the oil is still warm.
2. Loosen the transmission oil filter cover and allow oil to drain thoroughly. Do not completely remove the cover until drainage is complete.
3. Remove cover and filter and install new filter.
4. Pour eight quarts of Hydraulic Transmission Fluid "Type A" or Automatic Transmission Fluid "Type C" into the transmission.
5. Apply parking brake and position range selector in N and start engine.
6. Move range selector lever to Dr.
7. Run engine at normal idle speed and add sufficient oil to bring the level up to the "Add" oil mark on the dipstick.
8. With service brakes applied, shift the transmission through all ranges. Continue to run the engine until normal operating temperature of the transmission is attained. Then add oil, if necessary, to bring the level up to the "Full" mark.

Oil Cooler

The oil cooler (heat exchanger), through which the transmission oil is circulated before returning to the oil pan, dissipates the heat created by normal operation of the torque converter, transmission and hydraulic retarder. The cooling medium is the engine coolant.

When a clutch failure or other internal trouble has occurred in the transmission, any metal particles or clutch plate material that may have been carried into the oil cooler should be removed from the system by flushing the cooler before the transmission is put back into service. Foreign matter in the oil cooler could block off the front pitot feed hole, get into various gears and clutches, or block off the output shaft bushing lubrication orifice in the splitter shaft.

1. Disconnect both oil cooler lines at the fittings in the hydraulic retarder valve body.
2. Back-flush the oil cooler and lines with clean solvent and compressed air. *Do not exceed 100 psi air pressure.* An engine de-sludge gun may be used for flushing.
3. Remove all remaining solvent from the system with compressed air.
4. Flush the system again with Automatic Transmission Fluid. If, after the final flushing, there is no flow through the cooler, or if the flow is restricted, replace the radiator.

Transmission Repair Section

"IN TRUCK" REPAIRS

Servicing the fluid filter, oil pan, valve body, oil transfer plate and hand brake may be performed without removing the transmission from the truck.

When removing or installing the parking brake drum with the transmission in the truck, the rear pitot tube must be loosened to prevent damage to the rear governor. Loosen both rear pitot tube retaining screws four turns. *Do not turn these screws outward more than four turns as the pitot tube may fall off the screws.* Be sure that the screws and

Fig. 5 Valve body and oil transfer plate

Fig. 6 Hydraulic retarder rotor

Fig. 7 Splitter mechanism

pitot tube are not binding or sticking on the housing.

TRANSMISSION, DISASSEMBLE

After removing the transmission from the truck, mount the transmission in a suitable repair stand and disassemble as follows:

1. Remove fluid filter.
2. Remove oil pan.
3. Remove range selector valve body, Fig. 5. *The shift valve steel detent ball and spring and the rear pump nylon ball are free to fall out of the valve body when it is removed from transfer plate.*
4. Remove downshift timing valve body.
5. Remove oil transfer plate. *A nylon ball in the plate is free to fall when the plate is removed.*
6. Remove hydraulic retarder valve body. *Remove nylon ball from housing.*
7. Remove converter pump cover, lock-up clutch back plate and clutch plate.
8. Remove hook-type seal and snap ring from turbine shaft and then remove turbine.
9. Remove first stator. *Each stator contains eight springs and eight rollers which may fall out when stator is removed.* Remove bronze spacing washer.
10. Remove second stator and roller race.
11. Remove snap ring and spacer from converter ground sleeve, then lift out converter pump.
12. Lift off converter housing, being careful to avoid dropping the retarder rotor and shaft. *If this assembly lifts with the housing, tap the end of the shaft to dislodge it from the housing so it will remain in the transmission.*
13. Remove thrust washer from rear face of converter ground sleeve.
14. Lift out retarder rotor and shaft, Fig. 6.
15. Loosen bolt at top of transmission housing which anchors diaphragm in housing.
16. Remove low spitter clutch reaction plate, Fig. 6.
17. Remove splitter mechanism, Fig. 7.
18. Remove parking brake band.
19. Remove speedometer driven gear fitting from rear bearing retainer.
20. Remove two rear pitot tube mounting bolts (near brake anchor). *These bolts must be removed to allow the pitot tube to drop into the rear pitot collector ring before loosening the output flange retaining bolt and bearing retainer bolts to prevent damage to governor valves.*
21. Remove parking brake drum, Fig. 8.
22. Remove rear bearing retainer and rear pump. *Do not remove the reverse planetary carrier and rear pitot collector ring with the retainer; be sure they remain on the output shaft.*
23. Remove rear pitot tube from collector ring.

Fig. 8 Brake drum removal

24. Remove reverse planetary carrier and rear pitot collector ring from output shaft. *Various clutch parts are color coded, and should be assembled in the same locations when the transmission is serviced to insure proper fitting.*
25. Remove reverse sun gear after removing thrust washer and snap ring.
26. Remove reverse clutch pressure plate and backing plate, and Belleville spring.
27. Working through openings in transmission housing, remove low range and reverse clutch piston housing, Fig. 9.
28. Remove low range clutch Belleville spring.
29. Remove reverse range sun gear shaft after removing snap ring.
30. Remove thrust washer and take out output shaft assembly.
31. Remove low clutch apply plate and low clutch plate.
32. Remove low clutch reaction housing after removing anchor bolt, Fig. 10.
33. Remove low ring gear and intermediate planetary carrier, Fig. 11.
34. Remove intermediate clutch piston housing after removing anchor bolt, Fig. 11.

Fig. 9 Low and reverse clutch piston housing

Fig. 10 Low clutch reaction housing

Fig. 11 Low ring gear and intermediate planetary carrier

Fig. 13 Rear bearing retainer installation. Guide bolts shown may be made from 1/4" brazing rod 6" long and threaded for a length of 3/8"

35. Remove intermediate clutch Belleville spring. Then remove apply plate, clutch plate and ring gear as a unit.
36. Remove reaction housing after removing anchor bolt from bottom of transmission.
37. Remove oil collector.
38. Remove range selector and throttle control levers as required.

Fig. 12 Clutches and gears

TRANSMISSION, ASSEMBLE

Low and Intermediate Clutches and Gears and Low and Reverse Clutch Piston Housing

1. If a housing shim was removed during disassembly, install the same shim.
2. Install oil collector with conical portion facing toward front of housing.
3. Install intermediate clutch reaction housing so that threaded anchor bolt hole is aligned with hole in bottom of transmission case.
4. Install intermediate ring gear with longer section of gear toward front of transmission and toward reaction plate, Fig. 12.
5. Install intermediate clutch apply plate. This plate has an oil collector ring installed at its inner diameter.
6. Install, *but do not tighten,* the intermediate clutch reaction housing anchor bolt.
7. Install intermediate clutch Belleville spring with convex side toward rear of transmission. *Make sure spring is centered pefectly on clutch apply plate on which it seats so the piston housing will seat properly around it.*
8. Install intermediate piston housing with piston facing Belleville spring and with tapped hole in piston housing in line with the corresponding anchor bolt hole in bottom of case.
9. Install, *but do not tighten,* the intermediate clutch piston housing anchor bolt.
10. Install low ring gear and intermediate planetary carrier, Fig. 11. Rotate assembly until planetary pinion teeth engage internal teeth of ring gear.
11. Install low clutch reaction housing, aligning the tapped hole in the plate with its corresponding anchor bolt hole in bottom of transmission case, Fig. 10. Install, *but do not tighten,* reaction housing anchor bolt.
12. Install clutch plate and clutch apply plate.
13. Install transmission output shaft assembly, engaging planetary pinion teeth with internal teeth of low ring gear.
14. Install bronze thrust washer on out-

Fig. 14 Checking reverse, low and intermediate clutch plate clearances

Fig. 16 Converter stack control spacer measurement

put shaft. Then install reverse sun gear shaft over output shaft. Mesh teeth on flange with internal teeth of ring gear.

15. Install new snap ring in internal groove of low ring gear. Then install low clutch Belleville spring with convex side toward rear of transmission. *Make sure spring is centered perfectly on clutch apply plate on which it seats so low and reverse piston housing will seat around it.*
16. Install low and reverse clutch piston housing, aligning tapped hole in piston housing with corresponding anchor bolt hole in bottom of transmission case, Fig. 9. *Do not install anchor bolt at this time.*

Reverse Planetary Gearing and Clutch

1. Install reverse clutch Belleville spring with concave side toward rear of transmission.
2. Before installing reverse clutch pack in housing, assemble it as follows: Place clutch apply plate on bench with flat surface up. Position reverse ring gear and clutch plate assembly on apply plate with longer section of ring gear external teeth up. Over these two parts position reverse reaction housing with slots down so slots engage clutch apply plate tangs. Install this assembly in transmission case, aligning tapped hole in reaction housing with corresponding anchor bolt in bottom of transmission case. *Do not install anchor bolt at this time.*
3. Install reverse sun gear on sun gear shaft and secure with new snap ring.
4. Install bronze thrust washer over output shaft.
5. Install reverse planetary carrier and rear pitot collector ring on output shaft. Make sure planetary pinions mesh with sun gear and reverse ring gear.

Fig. 15 Converter pump cover installation

Selecting Proper Rear Bearing Retainer Gasket

1. With rear pump and speedometer drive gear removed, install rear bearing retainer, *without gasket,* on rear of transmission case.
2. Install four bearing retainer mounting bolts at 90° intervals, and tighten them to 85 *inch-pounds* torque.
3. Check clearance between bearing retainer and rear surface of transmission case near points where bolts are installed. This clearance will determine which gasket or gaskets to use. Gaskets are available in .012″, .016″ and .021″ thickness.

Fig. 17 Hydraulic retarder valve installation

4. If the measured clearance is .005-.015″ use .012″ gasket. If clearance is .016-.021″ use .016″ gasket. If clearance is .022-.027″ use .021″ gasket. If clearance is .028-.029″ use one .012″ and one .016″ gasket.
5. Install, *but do not tighten,* low and reverse clutch piston housing anchor bolt and reverse clutch reaction housing anchor bolt.
6. Remove bearing retainer.
7. Tighten five anchor bolts installed in bottom of transmission case to a torque of 10 lbs. ft.

Fig. 18 Oil transfer plate installation

Fig. 20 Range selector valve body installation

Rear Bearing Retainer, Brake Drum and Output Flange

1. Install correct bearing retainer gasket.
2. Install two guide bolts in rear pitot tube, making sure open (drilled port) side of pitot tube is toward bolts.
3. Place pitot tube in rear pitot collector ring with tube portion toward vanes and guide bolts toward rear of transmission, Fig. 13.
4. Carefully lower rear bearing retainer over output shaft while guiding guide bolts through pitot tube mounting bolt holes in retainer. It also will be necessary to guide rear pump drive lugs into driving slots in reverse planetary carrier and to start speedometer drive gear and spacer on output shaft. *Do not remove guide bolts at this time. Do not turn output shaft until flange retaining bolt is installed, otherwise damage to pitot tube and governor vanes may result.*
5. Install rear bearing retainer bolts and torque to 42-50 lb. ft.
6. Remove low and intermediate and reverse clutch reaction housing anchor bolts and, using a narrow feeler gauge in bolt holes and narrow screwdriver, separate apply plates and friction clutch plates in each range and measure clearance between them, Fig. 14. Clearance for intermediate range should be .020-.030″. A minimum clearance of .008″ in the low and reverse clutches and .018″ in intermediate clutch is allowable. If clearances are correct, install anchor bolts removed and torque them to 35-40 lb. ft.
7. Torque two piston housing anchor bolts to 17-20 lb. ft.
8. Remove one pitot tube guide bolt and start one mounting bolt, while holding out firmly on remaining guide bolt. Now, hold out firmly on mounting bolt, which has just been started, and remove remaining guide bolt. Then start other mounting bolt. *Do not tighten mounting bolts at this time.* The bolts should protrude $\frac{1}{16}$″ or more.
9. Install output flange and parking brake drum. *Do not turn output shaft while installing these parts; if shaft is turned, pitot tube or governor may be damaged.*
10. Install O-type ring seal, tab washer and output shaft bolt. Tighten bolt to 10 lb. ft. torque, being careful not to allow drum to rotate while tightening.
11. Torque pitot tube bolts to 10-12 lb. ft.
12. Torque output flange bolt to 83-100 lb. ft.
13. Install speedometer fitting in rear bearing retainer.

Splitter Mechanism, High Clutch and Power Take-Off Gear

1. Position transmission with front surface facing upward.
2. Install splitter mechanism, Fig. 7. The three anchor bolt holes in the high clutch diaphragm must align with the three transmission case holes, two in the bottom and one hole in the top of the housing.
3. Install three anchor bolts, the shorter one at top of transmission. Tighten two bottom bolts to a torque of 17-20 lb. ft. *Do not tighten the top bolt at this time; failure to tighten bolts in the correct order may cause internal oil leakage.*

Hydraulic Retarder

1. Install low splitter reaction plate with vanes toward front of housing and anchor bolt hole in line with hole in bottom of housing.

Fig. 19 Oil transfer plate attaching bolts

2. Install reaction plate anchor bolt and torque to 17-20 lb. ft.
3. Tighten diaphragm anchor bolt at top of housing to 17-20 lb. ft.
4. Install hook-type ring seal around splitter ring gear of turbine shaft and retarder rotor, Fig. 6.
5. Make sure thrust washer is in front of splitter planetary carrier and that the hook-type seal ring is in the groove at front of splitter output shaft. Oil the thrust washer and hook seal, then install turbine shaft and retarder rotor.

Torque Converter

1. Place converter housing gasket on transmission case.
2. Remove converter pump and hub. *Converter pump should be installed within one hour after removal while seal is still pre-stretched.*
3. The bronze thrust washer should

be checked to be sure it is being held in place at the rear of the ground sleeve by oil soluble grease. Install converter housing on transmission case and torque mounting bolts to 42-50 lb. ft.

4. Install hook-type seal ring on converter pump hub.
5. Install converter pump. Make sure slots in hub mate with front pump drive lugs and that hook-type ring seal on hub passes through front pump seal without damage to seal ring or seal.
6. Install seal in groove just inside bolt circle.
7. Install freewheel race spacer on ground sleeve with concave side up.
8. Install new snap ring to retain freewheel race spacer, then install freewheel roller race on ground sleeve.
9. Carefully install second stator. When installed, stator should freewheel in direction of arrow on converter pump, and lock when turned in opposite direction.
10. Install bronze spacer washer, then install first stator over roller race so that springs and rollers do not fall out. The first stator, when installed, should freewheel in the direction of the arrow on the converter pump, and should lock when turned in the opposite direction.
11. Install turbine on turbine shaft, Fig. 15.
12. Install snap ring and hook-type ring seal on turbine shaft, Fig. 15.
13. Install seal ring in groove just inside bolt circle on front of lockup clutch reaction plate.
14. Install reaction plate, Fig. 15. *If inked balance marks are found on reaction plate, converter pump, lockup piston and pump cover, assemble the parts with the marks aligned.*
15. Install lockup clutch plate on reaction plate with internal teeth engaging turbine splined ring, Fig. 15.
16. Install pump cover on converter pump studs. *If balance marks are on cover and pump, align balance marks.* Install four nuts at 90° intervals and tighten alternately to 10 lb. ft. to prevent synthetic seal from being forced out of its groove. install remaining nuts and torque all nuts to 19-23 lb. ft.
17. If any of the parts listed below are replaced in the course of the work, the dimension indicated by "A" in Fig. 16 must be checked. The required dimension is 1.572-1.592". Parts replacement which may affect dimension "A" are: Converter pump cover assembly, lockup clutch reaction plate, converter pump, converter pump hub, converter ground sleeve assembly and converter housing. Dimension "A" may be checked by fastening a sling as shown and applying a pull of 100 lbs. or more to remove all end play. If the dimension is not within specified limits, install or remove converter stack control spacers as needed. Spacers are furnished in five thicknesses ranging from .027" to .101".

Oil Transfer Plate, Valve Bodies, Oil Pan and Filter

1. Install hydraulic retarder valve body and nylon ball, Fig. 17. Tighten mounting bolts to 15-18 lb. ft.
2. Install oil transfer plate as shown in Figs. 18 and 19. Tighten bolts to 8-10 lb. ft.
3. Install downshift timing valve body on oil transfer plate and torque bolts to 8-10 lb. ft.
4. Install range selector valve body as shown in Fig. 20 and torque bolts to 4-6 lb ft.
5. Place new seals on both pump pickup tubes and install oil pan, torqueing bolts to 8-10 lb. ft.
6. Install fluid filter and tighten nut to 8-10 lb. ft.

Sub-Assemblies, Overhaul

CONVERTER PUMP COVER & LOCKUP CLUTCH

Disassemble

1. Remove lockup clutch reaction plate, Fig. 21, and lift out clutch plate. Tap edge of cover against wooden block, if necessary, to remove reaction plate.
2. Remove seal ring from front flange of reaction plate.
3. Remove snap ring which retains lockup clutch piston in pump cover.
4. Remove piston from pump cover by tapping edge of cover against a wooden block.
5. Remove seal from outer groove in piston.

Assemble

1. Install seal ring in outer groove in lockup clutch piston, then apply a light coat of oil to the seal.
2. Install piston in converter pump cover so that dowel holes in piston engage dowels in cover, Fig. 22. Be sure that balance marks on both parts are also aligned. *If the dowels do not enter the dowel holes, the lockup clutch will not disengage and the converter will not function.*
3. Install snap ring. If piston does not push far enough into the pump cover to install the snap ring, use a suitable sleeve and press ram to compress the piston.

CONVERTER PUMP

Disassemble

1. Remove large seal ring from converter pump, Fig. 23.
2. Tap out all damaged or worn converter pump bolts. Only damaged bolts should be removed from the pump. *Do not lose the positions of the balance weights.*
3. Remove bearing retainer from pump.
4. Tap hub from pump.
5. Remove synthetic seal ring from pump and hook-type seal ring from hub.
6. Drive bearing from hub, using a soft drift and light hammer.

Assemble

1. If any pump cover bolts were removed, insert new bolts and press them in place. Install balance weights in their proper positions.
2. Install new synthetic seal ring in outer groove of pump face just inside pump circle.
3. Install new seal ring on hub mounting surface groove of pump.
4. Install bearing in pump hub and position hub in pump.
5. Install bearing retainer on hub, align mounting holes, and install bolts, tightening them to 9-11 lb. ft. torque. *Do not install the hook-type seal ring in the pump hub at this time as the converter pump hub is to be used to pre-fit the front pump oil seal.*

Fig. 22 Lockup clutch piston and converter pump cover balance marks and dowels

CONVERTER STATORS

Disassemble and Inspect

Remove the springs or rollers which did not fall out of the stators during removal.

Fig. 23 Converter pump

Check both stators for cracks or excessive wear. Check springs and rollers for nicks, burrs or other damage.

Assemble

1. Apply oil soluble grease in stator cam pockets, then place roller springs in openings with open ends facing stator bore.
2. Compress springs with a small screwdriver to allow roller to be inserted in shallow end of each cam pocket. Install one spring and roller in each of the eight cam pockets in each stator. *Be sure springs and rollers are properly installed in roller race so that stators lock when they are turned in opposite direction*

Fig. 25 Splitter mechanism, high clutch and power take-off drive gear

Fig. 21 Torque converter, lockup clutch and front pump

Fig. 24 Front pump body

of engine rotation, and that they freewheel when turned in direction of engine rotation.

CONVERTER HOUSING & FRONT PUMP

Disassemble

1. Remove front pump body and gears from housing, Fig. 24.
2. Lift pump cover and seal ring out of converter housing.
3. Remove gears from pump body and drive seal ring out the front of pump body.
4. Unfasten converter ground sleeve from converter housing, using a wood block to drive sleeve from housing.

Assemble

1. Align the holes in the ground sleeve with the holes in the converter housing by installing two headless bolts in the converter housing.
2. Place the sleeve through the rear of the housing so the bolt holes slip over the headless bolts.
3. Using a wood block against the rear of the sleeve, drive the sleeve tight against the housing.
4. Remove the headless bolts and install the retaining bolts, tightening them to a torque of 17-20 lb. ft.
5. Coat a new front pump seal with Permatex on the outer diameter. Start seal into front bore of pump body.
6. Support machined rear face of pump body on a flat surface and press seal into body. *Use a hand press for this operation as a hydraulic press may damage the seal.* Press seal into body until there is 1.595-1.605" from front surface of seal to rear machined surface of pump body.
7. Place gears in pump body.
8. Position pump cover and install two guide bolts in body.
9. Install square section O-type seal ring aroung pump cover.
10. Place pump in front of converter housing and insert guide bolts through proper holes in housing and install four bolts with lock washers through rear of converter housing into pump body.
11. Remove guide bolts, install two remaining bolts and tighten all bolts to a torque of 15-18 lb. ft.
12. With hook-type seal ring removed from converter pump hub, align slots in hub with pump drive lugs and insert hub through seal. *Leave these parts assembled in this manner until ready for final assembly.*
13. Using oil soluble grease to hold bronze thrust washer in place, position washer in rear of ground sleeve.

Fig. 26 Low splitter clutch piston

Fig. 27 High clutch diaphragm installation

SPLITTER MECHANISM, HIGH CLUTCH & PTO DRIVE GEAR

Disassemble, Fig. 25

1. Remove low and intermediate sun gears after removing snap ring.
2. Grasp unit with fingers under high clutch and the thumbs over low splitter clutch friction plate to prevent it falling apart; then place it on blocks.
3. Remove thrust washer and snap ring. Then remove splitter planetary carrier and thrust washer.
4. Remove high splitter clutch and low splitter clutch friction plate.
5. Remove high splitter clutch back plate after removing snap ring.
6. Remove clutch plates and low splitter clutch friction plate.
7. Place high splitter clutch housing in press, supporting rear of housing and compress piston Belleville spring and remove snap ring. *When releasing Belleville spring pressure be sure that spring does not catch in snap ring groove.*
8. Remove Belleville spring and tap forward edge of clutch housing against wood block to remove high splitter piston.
9. Remove synthetic seal ring from piston and hook-type seal ring from housing.
10. Remove thrust washer and two hook-type seal rings from diaphragm, Fig. 26.
11. Remove splitter output shaft assembly, doing so slowly so that hook ends of seal rings do not break off.
12. If necessary, remove two wire snap rings and three hook-type seal rings.
13. Support rear of high clutch housing in a press and compress low splitter clutch piston Belleville spring and remove snap ring. Carefully release pressure on Belleville spring to keep its inner edge from catching in snap ring groove. *Do not attempt to lift diaphragm from assembly at this time as the vanes in the front fluid velocity governor may be damaged by the pitot tube.*
14. Remove assembly from press and lift out Belleville spring.
15. Remove low splitter clutch piston from high clutch diaphragm and remove synthetic seal ring from piston and hook-type seal ring from diaphragm. *Do not attempt to remove diaphragm from assembly.*
16. Remove the two front pitot tube mounting screws and lockwashers from front surface of diaphragm to allow pitot tube to drop into front governor collector ring. Lift diaphragm from assembly and remove two hook-type seal rings from rear of diaphragm. Remove pitot tube from collector ring.
17. Support front surface of high clutch housing assembly in a press, using a suitable block in center of housing so that governor collector ring will not be damaged. Compress piston return spring retainer and remove snap ring. *Release pressure on piston return spring retainer slowly, making sure inner edge of spring retainer does not catch in snap ring groove as spring expands.*
18. Remove assembly from press and lift off retainer and spring.
19. Remove large internal snap ring from high clutch housing.
20. Remove high clutch reaction plate, three internal splined plates, two external splined plates and the power take-off gear.
21. Tap rear of housing on a wood block to loosen high clutch piston. Remove piston, then remove synthetic seal from piston and hook-type seal ring from housing.

Assemble, Fig. 25

1. Install hook-type seal ring on high clutch housing and synthetic seal ring on high clutch piston. Coat seals lightly with oil.
2. Install piston in housing.

Fig. 28 Low splitter clutch plate installation

Fig. 29 Rear bearing retainer and rear pump

3. Support front surface of piston housing in a press, using a suitable block at center of housing so that governor collector ring will not be damaged.
4. Position coil-type piston return spring on top of piston, set retainer on spring and, using a suitable sleeve on the retainer, align the hole in the retainer with the hub of the housing. Then center the sleeve tool on the retainer. Compress the spring until the retainer is below the snap ring groove and install the snap ring. *Make sure the inner edge of the retainer does not catch in the snap ring groove.*
5. Install snap ring in housing hub groove and slowly release pressure on retainer. *Make certain snap ring is fully seated and that the retainer is straight and returns firmly against snap ring.* Remove assembly from press.
6. Install power take-off gear, aligning drive slots with slots in high clutch housing.
7. Install high clutch plates.
8. Install high clutch reaction plate so that the two longer tangs engage drive slots in power take-off gear.
9. Install large internal snap ring in high clutch housing to retain high clutch reaction plate.
10. Install two hook-type seal rings on rear of high clutch diaphragm.
11. Install high clutch with front governor collector ring facing upward.
12. Install two guide bolts in front pitot tube on the side of pitot tube that the drilled port is located, Fig. 27. (Guide bolts can be made from two 5-inch lengths of $\frac{3}{16}$" brazing rod threaded with a 10-32 die a distance of $\frac{3}{8}$".)
13. Place pitot tube in governor collector ring with intake port toward outer diameter of ring.
14. Install high clutch diaphragm over high clutch. Make sure diaphragm enters high clutch housing without damaging hook-type seal rings at rear of diaphragm. At the same time, direct guide bolts through pitot tube mounting screw holes, Fig. 27.
15. While holding up firmly on one of the guide bolts, remove other guide bolt and install pitot tube mounting screw and lockwasher. Tighten screw just enough to keep pitot tube from moving. Remove other guide bolt and install other mounting screw. Tighten both screws 38-48 lb. ft. torque. *Do not separate this assembly while pitot tube is in position.*
16. Install synthetic seal ring on low splitter clutch piston and the hook-type seal ring on low splitter piston housing side of diaphragm.
17. Lightly coat seal rings with oil and carefully install low splitter piston into diaphragm so that seal rings are not damaged.
18. Place assembly in press with low splitter clutch piston up. Then install the Belleville return spring on piston with convex side up. Compress spring carefully far enough to install snap ring. *Do not allow Pelleville spring to catch in snap ring groove while compressing spring.*
19. Place high clutch and diaphragm assembly on blocks. Install two wire snap rings and three hook-type seal rings on splitter output shaft. Lightly coat seal rings with oil and carefully install splitter shaft so that seal rings are not damaged.
20. Install hook-type seal ring on inner diameter of high splitter clutch housing and gear.
21. Install synthetic seal on outer diameter of high splitter piston.
22. Lightly coat seals with oil and install piston in housing, being careful not to damage seals.
23. Place piston and housing assembly in a press with piston up. Then install Belleville spring on piston with convex side up. Compress the spring carefully and only far enough to install the snap ring. Remove from press.
24. Install low splitter clutch friction plate on high splitter clutch housing so that the six internal tangs do not engage the slots in the housing where the high splitter piston tangs are located, Fig. 28. If the tangs through error are installed in the same slots, both splitter clutches would be applied when the high splitter piston is actuated.
25. Install two internal splined plates and one external splined plate.
26. Install high splitter clutch back plate, retaining it with large snap ring.
27. Install two hook-type seal rings and the bronze thrust washer on the front face of the diaphragm, then apply a light coat of oil to these parts.
28. Install high splitter clutch and low splitter clutch friction plate, being careful not to damage seal rings.
29. Coat bronze thrust washer with oil soluble grease and install in splitter planetary carrier.
30. Install splitter planetary, splining it on splitter output shaft and meshing with external teeth of high splitter clutch plates. Install snap ring on splitter shaft.
31. Lightly coat bronze thrust washer with oil and install on splitter planetary carrier.
32. Remove splitter assembly from blocks and place it on its side. *Be careful in handling the low and intermediate sun gears until they are installed and retained by snap rings so that the front pitot tube will not damage the front governor collector ring.*
33. Install low and intermediate sun gears. Then while holding splitter shaft by opposite end, install snap ring to retain sun gears.

TRANSMISSION REAR SUB-ASSEMBLIES

Rear Bearing Retainer & Rear Pump

1. To disassemble, Figs. 29, 29A, and remove pump from bearing retainer.
2. Remove pump cover and speedometer drive gear.
3. Pry out output shaft flange seal from retainer and remove internal snap ring.
4. Drive ball bearing out through rear of retainer; spacer washer will come out with retainer.
5. To assemble, install steel spacer washer in retainer.
6. Press ball bearing in retainer until

it is tight against shoulder in retainer.

7. Install bearing retainer snap ring.
8. Coat outside diameter of output shaft flange oil seal with Permatex and install seal so it is 1/32-3/64" above rear surface of retainer. *Do not assemble rear bearing retainer further until it has been used in the selection of the proper retainer-to-transmission gasket; this procedure is outlined under Transmission, Assemble.*
9. Install speedometer drive gear.
10. Install two guide bolts in rear bearing retainer. Then place pump cover over guide bolts. Install gears in pump body and slip pump body over guide bolts.
11. Start two of the pump retaining bolts, remove guide bolts and install other three bolts. Tighten all bolts to a torque of 15-18 lb. ft.

Reverse and Intermediate Clutch Plates and Ring Gears

1. To disassemble, straighten the clutch plate retainer ring at either side of the plate and remove the ring. Lift plate off gear. Then straighten and remove other ring.
2. To assemble, position clutch plate between the two grooves cut around the outside diameter of the ring gear. Place a new clutch plate retainer ring in one of the two grooves and crimp the ring at five evenly spaced intervals around the gear. Turn assembly over and install the other ring in the same manner as the first ring. *Do not crimp rings where cutouts are made in friction facings.*

Low, Reverse or Intermediate Piston Housing

1. To disassemble, tap edge of housing on wood block to loosen pistons and remove pistons from housings. Remove synthetic seal ring from outer groove of piston and hook-type seal ring from housing (or from piston in the case of the intermediate piston).
2. Assemble in the reverse order, lightly coating seals with oil and pushing them all the way into the housings.

Fig. 29A Rear bearing retainer and parking brake. Note that no rear pump is used with this assembly

Fig. 30 Checking range clutch clearances

Low Ring Gear and Intermediate Planetary Carrier

1. To disassemble, remove snap ring from low ring gear and lift out intermediate planetary carrier.
2. To assemble, mesh the teeth of the carrier with the teeth of the ring gear and push the carrier into the ring gear. Install the snap ring to hold the assembly together.

Checking Clutch Clearances

It will be necessary to check the clutch clearances if any pistons, piston housings, apply plates, reaction housings, Belleville springs, or clutch plates have been replaced in the low, intermediate or reverse clutches. This check is performed before assembly of the clutches in the transmission housing, using the tool shown in Fig. 30. It is advisable to check these clutches on every rebuild or teardown to be certain the clutches meet the proper clearance specifications.

Assemble the clutches in the tool as shown in Fig. 30. Then check the clearances as follows:

1. Use a small screwdriver to separate the plates. Then measure the clearances between the clutch friction plates and apply plates of the reverse clutch with a feeler gauge. This clearance should be .010-.015".
2. Repeat this operation on the low clutch, the clearance of which should also be .010-.015".
3. Use the same procedure to check the intermediate clutch, the clearance of which should be .020-.030".
4. If the clutches do not have the specified clearances, it will be necessary to replace the apply plates, which are available in three thicknesses for

Fig. 31 CONTROL VALVE BODY
(boxed-in parts used on school bus)

each clutch: .338-.342", .345-349" and .352-356".

5. Measure the maximum thickness of the apply plate from the clutch stack and, by considering the clearance measurement taken while the stack is assembled, choose the correct plate to bring the clearance within specifications.
6. Establish the correct clutch clearances for the three ranges. Then remove the clutch pack from the fixture and stack them on the bench in the reverse order. Now, each part may be selected in the correct order for assembly in the transmission housing.

HYDRAULIC VALVES OVERHAUL

Oil Transfer Plate

Referring to Figs. 31, 32, remove lube supply cover, converter pressure regulator valve retainer, spring, seat and steel ball. The low range clutch exhaust regulator valve is pressed into the oil transfer plate and should not be removed unless it is to be replaced with a new one. Check the operation of the valve while cleaning the transfer plate. The valve should retain the cleaning solvent on the side opposite the spring for at least 15 seconds.

Fig. 32 Oil transfer plate

106. Selector valve detent spring
107. Nylon ball (1/2")

Fig. 34 Range selector valve body

When assembling, tighten the lube supply cover screws to a torque of 24-36 inch-lbs. *The nylon ball is installed from the other side of the oil transfer plate when the plate is assembled to the transmission.* Tighten converter pressure regulator valve retainer screws to a torque of 24-36 inch-lbs.

Downshift Timing Valve

Remove this valve as indicated in Fig. 32. When assembled, tighten the cover screws to a torque of 24-36 inch-lbs.

Range Selector Valve Body

In servicing this valve, refer to Figs. 33 and 34. Also do not mix the various springs located in the valve body. Fig. 35 identifies the springs and balls and their dimensions.

When disassembled, wash all parts in cleaning solvent and dry thoroughly with air pressure. Check all parts and castings for cracks, nicks or burrs. Replace any cover or casting that is cracked or damaged. Remove any nicks or burrs with a fine stone.

Do not sand or polish any radius on the valves or plugs. The valves and plugs are manufactured with a sharp edge to prevent dirt from sticking in the valve bore.

All valves and plugs should be installed dry and must move in the valve body bore by their own weight. Do not attempt to force any valves into the bores as damage to the casting will result. If any valve or plug sticks, remove it and recheck for nicks or burrs.

When installing the front cover to the range selector valve body, check the mating surfaces between these parts. Be sure there is a tight seal and that none of the springs are caught between the housings. The front cover should not protrude above the main valve body face since it assembles against the oil transfer plate. Tighten all screws to a torque of 24-36 inch-lbs.

Check the mating surface between the valve body rear cover and range selector valve body. Be sure there is a tight seal and the intermediate shift valve spring is not caught between the housings.

If the rear cover and range selector valve body are in proper position (not distorted), tighten the screws to a torque of 24-36 inch-lbs., starting at the center of the cover and working toward the ends.

Fig. 33 Range selector and exhaust regulator valve bodies

SPRING	FREE HEIGHT (Inches)	NUMBER OF COILS
1. EXHAUST FEED PLUG	5.00	12½
2. SPLITTER RELAY VALVE	4.59	15½
3. MAIN PRESSURE REGULATOR VALVE (Outer)	4.46	16
4. MAIN PRESSURE REGULATOR VALVE (Inner)	3.67	13½
5. SPLITTER SHIFT VALVE	3.25	13
6. CONVERTER PRESSURE REGULATOR VALVE (Ball)	3.14	13½
7. LOCKUP CUT-OFF VALVE	2.50	12½
8. LOCKUP SHIFT VALVE	2.22	18½

SPRING	FREE HEIGHT (Inches)	NUMBER OF COILS
9. LOW-TO-INTERMEDIATE SHIFT VALVE	2.34	13½
10. INTERMEDIATE-TO-HIGH SHIFT VALVE	1.82	6
11. LOW-SPLITTER EXHAUST REGULATOR VALVE	1.72	8½
12. INTERMEDIATE EXHAUST REGULATOR VALVE	93	6
13. THROTTLE VALVE	1.210	11
14. RANGE SELECTOR VALVE DETENT	1.161	12
15. DOWNSHIFT TIMING VALVE	2.15	17

1. CONVERTER PRESSURE REGULATOR VALVE (STEEL) 5/16 INCH
2. REAR PUMP CHECK VALVE (NYLON) ½ INCH
3. and 4. RANGE SELECTOR VALVE DETENT (STEEL) ⅜ INCH
5. LUBRICATION SUPPLY CHECK (NYLON) ⅜ INCH
6. SPLITTER RELAY CHECK (NYLON) ¼ INCH (INSTALLED IN RANGE SELECTOR VALVE BODY FRONT COVER)
7. EXHAUST FEED PLUG PASSAGE CHECK (STEEL) ¼ INCH

Fig. 35 Control valve body spring and ball identification

Fig. 36 Exhaust regulator valve body for trucks. See Fig. 31 for school bus

Fig. 37 Lube regulator valve retainer, spring and ball

The range selector valve body must now be checked with a straight edge. Place the straight edge on the surface that mates to the oil transfer plate (only the pump overage should be above the surface). If any of the cover assemblies protrude above this surface, the screws will have to be loosened and the cover shifted to a position below the range selector valve body surface.

Exhaust Regulator Valve

Refer to Fig. 36 when servicing this valve. When disassembled, do not tamper with the bronze exhaust feed filter since the valve body is easily damaged. Wash all parts with cleaning solvent and dry thoroughly with compressed air. Remove nicks or burrs with a fine stone. Replace any cover or casting which is cracked or damaged. Do not sand or polish any radius on valves or plugs as they are made with a sharp edge to prevent dirt from sticking in the valve bore.

All valves and plugs must be installed dry and must move in their respective bores by their own weight. If a valve or plug sticks, remove it and recheck for nicks and burrs. When completely assembled, tighten all screws to a torque of 24-36 inch-lbs.

Hydraulic Retarder Control Valve

1. To disassemble, place the valve body on wood blocks with the mounting surface down. Drive the pin out of the valve body, Fig. 37.
2. Place the valve body on a wood surface with valve pointing up. Then, using a soft hammer and rapid, light blows, drive the valve against the spring in the body.
3. Remove seal, valve and spring from valve body.
4. Loosen the lube regulator valve retainer by tapping lightly around the edge of the retainer. Then remove retainer, spring and steel ball, Fig. 37.
5. Assemble the valve in the reverse order of removal, referring to Fig. 38. The lube regulator valve retainer should be pressed in until the large diameter is flush with the mounting surface to .030″ maximum below the surface of the valve body.
6. Coat the outer shell of the new oil seal with Permatex and start the seal straight into the vlave body. Press the seal in until it is flush with the valve body.
7. After the assembly is completed, the valve must be in its normal position, against the retaining pin, after actuation.

DESCRIPTION

These transmissions combine a three-element torque converter and a hydraulically-controlled three-speed and reverse planetary gearbox, Figs. 1, 2. The drive is always through the torque converter and one of the planetary gear ranges.

The torque converter, Fig. 3, consists of an impeller (pump), a turbine and a stator. All these parts are enclosed and operate in a fluid-filled housing. When an aluminum torque converter is used the unit is air cooled by means of the fins. The steel torque converter, when used, is cooled by circulating the transmission fluid through a cooler located in the radiator lower tank.

The planetary gear train in all units transmit power from the torque converter turbine shaft to the transmission output shaft. Hydraulic clutches and servo-operated bands drive or hold certain gears to provide the various transmission output ratios.

SPRAG CLUTCH

Dual Range Units

The sprag clutch, Fig. 4, is incorporated in the pinion carrier on dual range transmissions, such as the Cruise-O-Matic. The outer race is fitted in the pinion carrier and is held in place by a snap ring. The inner sprag race is a machined surface on the center support.

The sprag clutch performs the function of the rear band in low ratio while in the "D" range on Ford-O-Matic, Loadflite and Metro-Matic.

When the torque from the engine is delivered through the front clutch, the torque reaction of the one-way sprag clutch causes it to lock up and hold the drum stationary, thus giving low gear ratio. At the time of the 1-2 upshift, the front servo is engaged and as soon as the front band picks up the reaction torque, the sprag clutch will start to free wheel and the transmission will be in second gear ratio.

The purpose of the sprag clutch is to aid in the timing of the 1-2 upshift and the 2-1 downshift.

TROUBLE SHOOTING

Severe Engagement In Low, Drive or Reverse

1. Improper idle speed.
2. Throttle linkage adjustment.
3. Incorrect oil pressure.
4. Defective valve body.
5. Oil pressure regulator.
6. Rear Band Adjustment.

Rough Start In Reverse

1. Improper idle speed.

Fig. 1 Sectional View of Transmission With Air-Cooled Torque Converter

Fig. 2 Transmission thrust washer locations

2. Throttle linkage adjustment.
3. Incorrect oil pressure.
4. Defective valve body.
5. Oil pressure regulator.
6. Rear band adjustment.

Shift Points From 1-2 and 2-3 Too High, Too Low or Erratic

1. Throttle linkage adjustment.
2. Defective governor.
3. Defective valve body.
4. Leakage in hydraulic system.

Severe Shift from Intermediate to Drive

1. Throttle linkage adjustment.
2. Front band adjustment.
3. Defective valve body.
4. Defective front servo.
5. Oil pressure regulator.

Engine Races from Intermediate to Drive

1. Throttle linkage adjustment.
2. Defective valve body.
3. Hydraulic system leaks.

No Downshift from Drive to Intermediate when Accelerator is Depressed

1. Throttle linkage adjustment.
2. Improper oil pressure.
3. Defective valve body.

Severe Shift from Drive to Intermediate with Throttle Closed

1. Throttle linkage adjustment.
2. Improper idle speed.
3. Defective valve body.

Excessive Creeping

1. Engine idle speed too high.

Slippage or Chatter in Intermediate

1. Throttle linkage adjustment.
2. Front band adjustment.
3. Improper oil pressure.
4. Defective valve body.
5. Oil pressure regulator.
6. Defective front servo.
7. Defective front clutch.
8. Hydraulic system leaks.

Slippage or Chatter in Low

1. Throttle linkage adjustment.
2. Rear band adjustment.
3. Improper oil pressure.
4. Defective valve body.
5. Oil pressure regulator.
6. Defective rear servo.
7. Defective front clutch.
8. Hydraulic system leaks.

Slippage or Chatter in D1 Only

1. Defective planetary one-way clutch.

Slippage or Chatter in Reverse

1. Throttle linkage adjustment.
2. Rear band adjustment.
3. Improper oil pressure.
4. Defective valve body.
5. Oil pressure regulator.
6. Defective rear servo.
7. Defective rear clutch.
8. Hydraulic system leaks.

Car Won't Move in D or D2

1. Front band adjustment.
2. Defective valve body.
3. Defective front servo.
4. Defective front clutch.

Fig. 3 Sectional view of torque converter (air-cooled)

5. Hydraulic system leaks.

Car Won't Move in D1 Only

1. Defective planetary one-way clutch.

Car Won't Move in Low or Reverse

1. Worn or defective rear band.
2. Inoperative rear servo.
3. Defective valve body.

Car Won't Move in Any Range

1. Low oil level.
2. Broken parking lock.
3. Defective valve body.
4. Oil pressure regulator.
5. Hydraulic system leaks.
6. Broken converter hub.

Locks In Reverse

1. Defective front clutch.
2. Check parking linkage.
3. Front band applied.

Locks in Low or Drive

1. Defective rear clutch.
2. Check parking linkage.
3. Broken parking pawl.

Parking Lock Will Not Hold

1. Manual linkage adjustment.
2. Check parking linkage.
3. Broken pawl operating lever.

Engine Won't Rotate When Car is Pushed

1. Oil pressure regulator.
2. Defective rear oil pump.
3. Hydraulic system leaks

Transmission Overheats

1. Restricted converter cooling air passage.
2. Rear band adjustment.
3. Oil pressure regulator.
4. Defective converter clutch.
5. Front band adjustment.

Engine Runaway on Forced Downshift

1. Defective valve body.

Noise in Neutral

1. Converter cover bolts striking.
2. Defective front pump.
3. Interference in converter.
4. Check parking linkage.

Noise in Low, Intermediate or Reverse

1. Defective planetary assembly.
2. Defective front clutch.
3. Defective rear clutch.

Noise when Coasting in Neutral at 20-30 MPH, Engine off

1. Defective rear pump.

Noise in Converter

1. Converter cover bolts striking.
2. Interference in converter.

Fig. 4 Pinion carrier, sprag clutch and center support used on dual-range units such as Cruise-O-Matic

MAINTENANCE

Adding Fluid

Use Automatic Transmission Fluid only. Check fluid level every 1000 miles. To check the level, place the selector lever in the P position. Start the engine and operate it for approximately four minutes or until the engine and transmission have reached normal operating temperature.

Remove the oil level inspection hole cover. Clean all dirt from the area around the dipstick. Apply parking brake and foot brake. Move selector lever slowly from P to R and then to D. Remove the dipstick, wipe clean, install in transmission and turn clockwise to the lock position. Remove the dipstick again and note the amount of fluid registered. Add fluid through the dipstick hole to bring the fluid level to the FULL mark on the dipstick.

Changing Fluid

The transmission fluid should be changed at 24,000-mile intervals. The procedure is as follows:

1. Remove cover from lower front side of converter housing.
2. Remove one of the converter drain plugs. Then rotate the converter 180 deg. and remove the other plug. *Do not attempt to turn the converter with a wrench on the converter stud nuts as there is danger of stripping threads as well as skinning your knuckles on the bell housing.*
3. When all fluid has drained, remove and clean the oil pan and screen.
4. Using a new pan gasket, install screen and pan.
5. Connect filler tube to oil pan and tighten fitting securely.
6. Install both converter drain plugs.

7. Install converter housing cover.
8. Install 5 quarts of Automatic Transmission Fluid.
9. Run engine at idle speed for about 2 minutes; then add the additional quantity of oil required for the particular transmission being serviced.
10. Run engine at a fast idle until it reaches normal operating temperature.
11. Shift the transmission through all postions; then place it at P and check fluid level. If necessary, add enough fluid to bring the level to the F mark on the dipstick.

"In Truck" Repairs

BAND ADUSTMENTS

The front and rear band of the transmission should be adjusted at 15,000 mile intervals or as operation of the transmission indicates.

Front Band

The tool shown in Fig. 5 is especially made for this adjustment. However, by using a piece of ¼" wide metal block and an ordinary end or box wrench a satisfactory adjustment can be made.

With transmission oil pan removed, back off adjusting screw lock nut and screw far enough to permit the ¼" metal block to be inserted between servo piston rod and adjusting screw. Turn screw with wrench until it contacts metal block. Then tighten adjusting screw a little more (equivalent to 10 inch lbs.) and back off one turn.

Rear Band

The tool shown in Fig. 6 is especially made for this adjustment. However, a satisfactory adjustment may be made by using a conventional torque wrench. Loosen lock nut and tighten adjusting screw to a torque of 10 lb. ft. Then back off the screw 1½ turns and tighten lock nut.

Fig. 7 Transmission case fluid passages

AIR PRESSURE CHECKS

A series of air pressure tests can be made on the transmission with the unit in the car. These tests are helpful in determining if clutches, bands and servos are operating in a normal manner.

To make the tests, drain the fluid from the transmission. Remove the transmission oil pan, screen and control valve assembly. The front servo tubes should remain in the front servo and the attaching screw must be tight. *When making tests, hold a clean towel over the transmission opening to prevent excessive oil spray.* Refer to Fig. 7 for oil passage locations.

Front Clutch

Apply air pressure to the front clutch passage. Listen for a dull thud which indicates the clutch is operating. Keep air pressure in the passage for several seconds to check for leaks in this circuit.

Governor Valve

Remove the governor inspection hole cover and apply air pressure to the front clutch passage. Listen for a click and watch the valve snap inward.

Rear Clutch

Apply air pressure to the rear clutch passage. Listen for a dull thud which indicates the clutch is operating. Keep air pressure in the passage for several seconds to check for leaks in this circuit.

Front Band and Front Servo

Apply air pressure to the front servo apply tube and observe band application.

Rear Band and Rear Servo

Apply air pressure to the rear servo and observe band application.

Results of Tests

If servos, bands, clutches and governor operation is normal with air pressure, the condition of *no drive, erratic upshifts or downshifts* points to the control valve assembly and pressure regulator valve. These should be disassembled, cleaned and inspected.

Fig. 5 Adjusting front band

Fig. 6 Adjusting rear band

Fig. 8 Oil pressure test take-off point

Fig. 9 Oil pressure regulator. 1955-59 single-range units

Fig. 10 Oil pressure regulator. 1958-59 Dual-Range units

OIL PRESSURE TESTS

The oil pressure tests should be performed to ascertain whether or not the pressure regulator system is functioning correctly and to determine if there is fluid leakage in the clutch circuits.

Remove the ⅛" pipe plug, Fig. 8, and install a pressure gauge. The gauge should be placed in the driver's compartment where it can be observed by the operator. Connect a tachometer to the engine where it can also be read by the operator. Then perform the following tests:

Idle Pressure Test

Start engine and operate until engine and transmission reaches normal operating temperature. With engine at idle speed, move the selector lever to D, L and R positions. The pressure gauge should read approximately 50 to 80 lbs. in all ranges.

If the pressure is low in any one range, an oil leak in that range circuit is indicated and must be corrected. If the pressure is high the throttle linkage should be checked and adjusted as outlined in the *Truck Chapter*.

Fig. 11 Oil pressure regulator. 1954 and earlier units

Fig. 12 Control valve body (upper). 1954 and earlier units

Fig. 13 Control valve body (lower). 1954 and earlier units

Fig. 15 Control valve body (upper). 1955 and later single-range units

Fig. 16 Front servo. 1955 and later single-range units

Pressure Regulator Check

Move the selector lever to the D range and firmly set the hand and foot brakes. Run the engine at 1000 rpm and read the pressure gauge. If the reading is less than 80 lbs. or more than 85 lbs. it indicates the throttle valve linkage must be readjusted. If the pressure is greater than 85 lbs. it indicates the throttle valve linkage is too short and must be readjusted.

Stall Pressure Tests

Firmly set the hand and foot brakes and operate the engine at full kickdown position. Move the selector lever to D, L and R ranges and read the pressure gauge. The pressure in the D and L positions should be 130 to 175 lbs., and 170 to 190 lbs. in the R range.

If the pressure is not within specified limits, malfunctioning of the throttle valve, modulator valve, compensator valve, or pressure regulator assembly is indicated and it will be necessary to remove and clean the control valve assembly and pressure regulator valve assembly.

OIL PRESSURE REGULATOR

Remove oil pan and screen. Maintain constant pressure on the spring retainer to prevent damage to springs and remove retainer from bosses on oil pressure regulator body. Remove springs and pilots. Remove the three pipes. Unfasten and remove the oil pressure regulator from the transmission case.

Disassemble the unit as shown in Figs. 9, 10, 11. After cleaning and inspecting parts, assemble the unit and tighten the regulator attaching bolts.

CONTROL VALVE

To remove the assembly, loosen the adjustments on the front and rear bands 5 or 6 turns. Loosen front servo attaching screws. Remove cap screws and washers which attach control control valve to case. Align throttle and manual levers to permit removal of control valve.

Fig. 14 Control valve body (lower). 1955 and later single-range units

Fig. 17 Front servo. Units with sprag clutch. Accumulator units not used on some 1961 and later units

Disengage front servo tubes from control valve and lift valve assembly from case.

When servicing the control valve it is recommended that each valve body of the assembly be disassembled, cleaned, inspected and reassembled one at a time. To aid in reassembly, it is also recommended that the parts of each body be placed on a clean bench in the order in which they are removed from the body.

Disassemble and assemble the unit as illustrated in Figs. 12 to 15.

When disassembled, clean all parts in each valve body thoroughly with solvent and blow dry with moisture-free compressed air. Inspect all valves and valve bores for scores and burrs. Check all fluid passages for obstructions. Inspect all mating surfaces for burrs or distortion. Inspect all springs for distortion.

Crocus cloth may be used to polish valves and plugs. However, care must be taken to avoid rounding the sharp edges of valves and plugs. Check all valves and plugs for freedom of movement in their respective bores. Valves and plugs, when dry, should fall from their own weight in their respective bores.

FRONT & REAR SERVOS

To remove the front servo, remove the cap screw which holds it to the case. Hold the actuating lever strut with one hand and lift the servo from the case.

To remove the rear servo, take out the attaching cap screws. Then hold the anchor strut and lift the servo from the case.

Front Servo Repairs

Disassemble the servo as shown in Figs. 16 and 17.

When disassembled, inspect the servo body for cracks, burrs and obstructed fluid passages. Inspect the piston bore and piston stem for scores. Inspect the actuating lever and shaft for wear and freeness in the servo body. Also inspect the adjusting screw threads and the threads in the actuating lever. Inspect the servo band for wear and bonding of the lining to the band. Replace the band if the grooves in the lining are worn even with the rest of the lining. Inspect the band ends for cracks or distortion. Install the piston and guide in the servo body and check for freedom of travel.

Minor burrs may be removed with crocus cloth. However, parts showing deep burrs, scores, scratches or excessive wear should be replaced.

Lubricate all parts with automatic transmission fluid before starting reassembly. Then assemble the unit as shown in Figs. 16 and 17.

Rear Servo Repairs

Disassemble the servo as shown in Figs. 18 and 19. Inspect the parts for the same conditions outlined for the front servo.

EXTENSION HOUSING SEAL

After removing the drive shaft, the seal may be pulled out of the extension housing.

Before installing the new seal, inspect the sealing surface of the universal joint yoke for scores. If scores are evident replace the yoke. Inspect the counterbore in the housing for burrs. Polish all burrs with crocus cloth.

To install the new seal, position it in the bore of the extension housing with the felt side of the seal to the rear. The seal may be driven into the housing with a special tool designed for the purpose.

OIL DISTRIBUTOR

With Bolted Distributor & Sleeve

After removing the extension case remove the spacer from the transmission output shaft and slide the distributor toward the rear of the transmission. Note that the tube spacer is located in the center tube.

Remove the three tubes and spacer from the distributor. Remove the screws which attach the distributor to the sleeve and separate these parts.

Inspect the distributor and sleeve for

Fig. 18 Rear servo. 1955 and later units

Fig. 20 Layout of governor parts

burrs on the mating surfaces and for obstructed fluid passages. Check the fit of the tubes in the distributor. Inspect the distributor sleeve for wear and scores in the sleeve bore.

To assemble, align the distributor and sleeve and install the cap screws. Install the tubes in the distributor with the spacer installed on the center tube.

With One Piece Distributor & Sleeve

After removing the extension housing, remove the distributor drive gear snap ring. Remove distributor gear, taking care not to lose the gear drive ball. Remove distributor sleeve and pipes from the transmission. Inspect the seal rings on the output shaft for wear or breakage, and replace if necessary. Inspect the distributor sleeve for wear and the tubes for proper alignment and fit into the distributor sleeve.

With tubes installed in the distributor sleeve, install distributor on output shaft (chamfer forward) sliding the distributor over the seal rings and at the same time guiding tubes into the case. Install speedometer drive ball and gear and install snap ring.

GOVERNOR

Remove the governor inspection cover from the extension housing. Rotate the drive shaft to bring the governor body in line with the inspection hole. Remove the two screws which attach the governor body to the counterweight and remove the body.

Remove the valve from the new governor body. Lubricate the valve with automatic transmission fluid. Install the valve in the body, making sure the valve moves freely in the bore. Install the body in the counterweight with the side plate forward. Be sure the fluid passages in the counterweight and body are aligned. Fig. 20 illustrates the entire governor assembly.

TORQUE SPECIFICATIONS

Location of Parts	Ft. Lbs.
Converter cover to impeller bolts	15-28
Converter to drive plate screws	23-28
Converter to flywheel nuts	15-28
Converter housing to case bolts	35-45
Distributor-to-sleeve screws	8-10
Front pump to case bolts	17-22
Front servo to case bolts	30-35
Rear servo to case bolts	40-45
Planetary support to case screws	20-25
Upper to lower valve body bolts	4-6
Valve body to case bolts	8-10
Pressure regulator to case screws	17-22

①—Inch pounds. ②—Single range units. ③—Dual range units.

Fig. 19 Rear servo. 1954 and earlier units

Repairs Requiring Transmission Removal

TRANSMISSION, DISASSEMBLE

1. Remove pressure regulator valve, vacuum diaphragm unit and push rod (if used), control valve assembly and both servos as outlined previously.
2. The next step is to check the mainshaft end play for future reference when reassembling the transmission. Remove one of the front pump retaining screws and mount a dial indicator so that the indicator button rests against the end of the input shaft. Use a large screwdriver to pry the front clutch to the rear and, while holding pressure against the screwdriver, zero the dial indicator. Insert the screwdriver between the parking gear and transmission case and pry the units toward the front of the case. *If end, play is not within the limits of .010" and .029", record the amount of end play present so that a suitable thrust washer may be installed to establish the correct end play when the transmission is reassembled.*
3. Unfasten and remove the front pump from the transmission case.
4. Remove extension housing and oil distributor.
5. Remove the oil distributor sleeve from the output shaft. Slip the four seal rings from the shaft. Remove the governor snap ring and slide off

Fig. 21 Removing rear pump discharge tube

Fig 23. Front pump assembly

Fig 24. Rear pump assembly

the governor, being sure not to lose the governor drive ball.

6. Remove rear pump inlet tube. Using tool shown in Fig. 21, remove outlet tube. Slide pump off output shaft and remove gasket and rear pump drive key, Fig. 22.
7. Hold pinion carrier in position and slide output shaft and internal gear toward rear of transmission. Remove thrust washer from pinion carrier. *This washer, supplied in various thicknesses, determines the end play of the mainshaft assembly.*
8. Hold pressure against primary sun gear shaft and remove pinion carrier by sliding toward rear of case. Remove thrust washer from inside of pinion carrier. *Note position of cone on inner diameter of thrust washer.*
9. Remove the two remaining cap screws which attach the center support to the transmission case. *These screws are located on the outside of the case.* Remove center support through rear of case.
10. Remove front clutch, rear clutch and sun gears as a unit. Remove the thrust washer from in front of the front clutch. Separate front and rear clutches and remove thrust washer and contour thrust washer from between clutches.
11. Remove and tilt front band and remove through bottom of case.

FRONT PUMP

When disassembled, inspect the pump body for excessive wear and scores. Inspect the internal and external tooth gears for scores, scratches and excessive wear. Inspect the stator support face for scores, scratches nad excessive wear.

Minor scratches and scores can be removed with crocus cloth. However, parts showing deep scratches, scores or excessive wear should be replaced.

Assemble the pump as shown in Fig. 23. Tighten the stator support attaching screws.

REAR PUMP

Before disassembling the pump, Fig. 24, mark the external and internal tooth gears with crayon or pencil to aid in reassembly. When disassembled, inspect all parts for wear or damage as outlined for the front pump.

When reassembling the pump, position the gears in the body with the marks made previously in the upward position.

OUTPUT SHAFT & INTERNAL GEAR

Remove the four piston ring type seals from the output shaft. The rings must be removed singly starting with the rearmost ring. While the output shaft and internal gear assembly is a two-piece unit, no further disassembly is required since the unit is serviced as an assembly.

Inspect the internal gear and parking gear for broken teeth and burrs on the thrust surfaces. Inspect the output shaft for burrs and scores on the bearing surfaces and ring grooves. Inspect the rear pump drive keyway and governor drive ball socket for wear.

Fig. 22 Location of rear pump drive key

Minor burrs and scratches may be removed with crocus cloth. However, parts having broken teeth, large burrs, scratches or scores, or showing evidence of wear should be replaced.

Install the four seal rings on the output shaft, starting with the foremost ring and working toward the rear.

PINION CARRIER

The pinion carrier is serviced as an assembly; therefore, there is no disassembly or assembly procedure. To check its serviceability, however, inspect the band surface and the inner and outer bushings for scores. Rotate the pinions on their shafts to check for freedom of movement and inspect for worn and broken teeth. Use a feeler gauge to check pinion end play which should be .010″ to .020″. Inspect pinion shaft for tightness to the pinion carrier.

CENTER SUPPORT

The center support is serviced only as an assembly. To check its serviceability, however, inspect for burrs or distortion, and the bearing surface for scores and scratches.

Minor burrs and scratches may be removed with crocus cloth. Any damage more serious than that requires replacing the support.

FRONT CLUTCH

Service Note

The number and type of clutch plates vary with vehicle make, model and engine. Be sure to obtain the correct clutch pack for the application being serviced.

Disassemble, Fig. 25, 25A

1. Remove clutch cover snap ring.

Fig. 25A Front and rear clutches and related parts for dual range units

2. Remove turbine shaft and fiber thrust washer from clutch hub.
3. Remove plates and clutch hub from drum; also clutch pressure plate.
4. Using a suitable spring compressor on clutch release spring, exert sufficient pressure to compress spring and remove snap ring.
5. Remove tool and clutch spring.
6. Apply air pressure to clutch inlet hole to force clutch piston out of clutch drum bore.
7. Remove rubber outer piston seal from piston and remove piston metal wear ring from piston.
8. Remove O-ring seal from clutch drum.

Inspection

1. Inspect turbine shaft and clutch hub for burrs on thrust surfaces, splines and serrations.
2. Inspect clutch piston for burrs, scores or cracks.
3. Inspect clutch drum for burrs on thrust surfaces and splines, and clutch bore for scratches and scores.
4. Inspect clutch release spring for cracks or distortion and pressure plate for cracks and scratches.
5. Inspect steel plates for burrs on serration and for wear, and for flatness.
6. The lined plates should be replaced when grooves in lining are no longer visible, as if plates are warped.

Assemble

1. Lubricate all parts with transmission fluid before assembly.
2. Install new O-ring seal in clutch drum and a new seal on clutch piston and install piston in clutch drum bore.
3. Press piston down lightly until it bottoms in bore, being careful not to damage outer piston seal.
4. Install metal wear ring on piston.
5. Install clutch spring on piston with concave side upward.
6. Position compressor tool on spring and exert sufficient pressure to compress spring so that snap ring can be installed. Use the thicker snap ring.
7. Remove compressor and install pressure plate with smooth side upward.
8. Install hub in drum bore with thrust surface upward.
9. Install lined plates and steel plates alternately, starting with a lined plate.
10. Coat fiber thrust washer with heavy grease to hold it in place and position it on clutch hub.
11. Align serrations of clutch cover and turbine shaft with serrations in drum and install cover and snap ring.

Fig. 25 Front and rear clutches and related parts for single range units

Fig. 26 Sprag clutch-to-center support installation

Fig. 27 Pinion carrier installation on units with sprag clutch

REAR CLUTCH & PRIMARY SUN GEAR

Service Note

The number and type of clutch plates vary with the vehicle make, model and engine. Be sure to obtain the correct clutch pack for the application being serviced.

Disassemble, Fig. 25, 25A

1. Remove two ring seals from primary sun gear shaft and remove rear clutch assembly.
2. Remove primary sun gear thrust washer and ring seals from sun gear shaft.
3. With a suitable spring compressor, exert sufficient pressure on clutch spring to compress it so that snap ring can be removed.
4. Remove the balance of the clutch parts.

Inspection

1. Inspect primary sun gear and shaft for burrs, scratches, worn ring grooves and broken teeth.
2. Use an awl to check front clutch lubrication ball check valve in front end of sun gear shaft for freedom of movement.
3. Inspect the balance of the clutch parts as outlined for the front clutch. However, check each steel plate for proper coning. Each plate is coned to .010″ to .020″ clearance. If any plate requires replacement, the entire clutch plate pack should be installed.

Assemble

1. Lubricate all parts with transmission fluid before assembly.
2. Install new inner O-ring seal on drum hub and new clutch outer seal on piston.
3. Install piston in drum bore.
4. Press piston down until it bottoms, being careful not to damage outer seal.
5. Install clutch spring and retainer.
6. Compress spring and install snap ring.
7. Install bronze plates and steel plates alternately, starting with a steel plate. Coned steel plates must face same direction; either all concave or all convex side up.
8. Install pressure plate with smooth side down and install snap ring.
9. Install two ring seals on short end of primary sun gear shaft.
10. Install sun gear thrust washer.
11. Install two ring seals on sun gear shaft adjacent to sun gear.
12. Position clutch on sun gear shaft.
13. Install two remaining ring seals on primary sun gear shaft.

TRANSMISSION CASE & LINKAGE

Remove linkage parts as required. Clean the transmission case thoroughly and blow out fluid passages with compressed air. Inspect the case for stripped threads, obstructed fluid passages, cracks, and mating surfaces for burrs. Inspect case bushings for scores, and linkage parts for wear or distortion.

TRANSMISSION, ASSEMBLE

When installing the sub-assemblies in the transmission case, no not use force to assemble mating parts. If the parts do not mesh freely, examine them for the cause of the difficulty. Always use new gaskets. Use only Automatic Transmission Fluid to lubricate parts.

Clutch Assemblies

1. Install front band in transmission case so that anchor end is aligned with anchor in case. Lift clutch assemblies out of holding block. *Do not allow clutches to separate.*
2. Install sub-assemblies in case from the rear while positioning servo band on drum. Hold units together while making installation.
3. Position center support in case, aligning hole in center support with hole in right-hand side of case.
4. Install right and left-hand center support outer bolts and external tooth lockwashers. *Lockwashers must be installed with rolled edge toward transmission case to insure a tight seal.*

Center Support, Sprag Clutch and Pinion Carrier

1. On the bench, install sprag clutch on center support with flange side of case rings up, Fig. 26.
2. Carefully compress each drag spring as it is started on the inner race. After all drag springs are started

Fig. 28 Layout of torque converter parts

Fig. 29 Removing converter pump hub

Fig. 31 Correct position of sprag in race

Fig. 30 Layout of stator parts

on race, rotate clutch to tilt sprags; then push clutch all the way down on center support. Place a strong rubber band around sprag outer ends, Fig. 27.

3. Install center support and clutch in case.
4. Position rear band in case. Install washer on thrust face inside pinion carrier.
5. Install pinion carrier in case and start pinion carrier front pilot in center support bushing. Depress the "T" bar and work pinion carrier forward until sprags are started on clutch outer race, Fig. 27.
6. Remove rubber band.
7. Work pinion carrier forward to the point that the sprag clutch is visible. Rotate pinion carrier counterclockwise (from rear) and note whether clutch rotates with pinion carrier or remains stationary with center support.
8. The clutch is so designed that the "T" bar frictional grip on the clutch outer race is stronger than the drag spring frictional grip on the inner race; hence the clutch should rotate with the pinion carrier. If it does not, replace the sprag clutch.

Pinion Carrier (Units Without Sprag Clutch)

1. Position rear servo band in case with strut ends up. Place anchor end with depression toward adjusting screw. Install a bronze thrust washer on thrust face inside pinion carrier.
2. To install pinion carrier, position rear band over drum while meshing planet pinions. Install the two seal rings on primary sun gear shaft and check rings for free movement in grooves.

Mainshaft End Play

If the end play was not within specifications when checked prior to disassembly, replace the washer with one of the proper thickness. The following selective washers are available in the following thicknesses:

.061″ to .063″
.067″ to .069″
.074″ to .076″
.081″ to .083″

After installing the proper washer, install the output shaft, carefully meshing the internal gear with the pinions.

Rear Pump

1. Put drive key in keyway on output shaft.
2. Place new front and rear gaskets on pump body.
3. Install thrust washer on pump body with bronze side up. Align thrust washer tangs with bosses on pump body and install rear pump.

Governor

Place governor drive ball in pocket in output shaft. Install governor, aligning groove with ball in output shaft. Install governor snap ring.

Install governor with governor body plate toward front of transmission.

Oil Distributor

1. Place four seal rings on oil distributor sleeve and check ring gaps to see that they are spaced equally around the sleeve. Check fit of seal rings in grooves in output shaft; rings should rotate freely. Install rings in grooves in output shaft.
2. Install three tubes in distributor sleeve. Install distributor sleeve on output shaft with chamfer forward. Slide sleeve forward over four rings and at the same time start tubes into case. The distributor sleeve is located between governor snap ring and speedometer drive gear.
3. Install new seal on rear pump outlet tube and install tube in transmission case and rear pump body.

Extension Housing

1. Position speedometer drive gear ball in pocket in output shaft. Install speedometer drive gear and retain gear in place with snap ring.
2. Insert extension housing oil seal replacer and pilot in housing; then install extension housing on transmission case. Install attaching bolts and external tooth lockwashers with rolled edge of washers toward transmission case to insure a tight seal.
3. Install governor inspection cover and a new gasket on housing.

Front Pump

Position new gasket in counterbore in front of transmission case. Install front pump, aligning pump bolt holes with holes in case. Install three of front pump attaching bolts.

Recheck transmission end play, which should be .010″ to .029″. Then install remaining pump bolt.

Final Assembly

Install progressively the front servo, rear servo, pressure regulator body, and control valve body as previously outlined. Then adjust front and rear bands. Finally, install oil screen and oil pan, using new gasket.

TORQUE CONVERTER

To remove the converter from the transmission, grasp the converter cover with both hands and pull straight out. To prevent damage to the front seal, do not rock the assembly from side to side. After removing the attaching bolts, the converter housing may be taken off the transmission.

Disassembly

Place the converter in a holding fixture. Note the location of the pump and cover aligning marks, then remove the cover attaching bolt, Fig. 28.

Remove the cover and gasket. Slip the bronze thrust washer from the pump housing. Lift out the stator, noting its position in the housing. Take the thrust washer from the pump hub.

To disassemble the stator, remove the one way clutch inner race. Release the snap ring which retains the outer hub to the stator. Remove outer hub, sprag assembly and outer race. Remove the snap ring retaining the inner hub to the stator and take out the inner hub.

To disassemble the pump, remove the bolts which attach the pump hub to the pump, Fig. 29. Take out the hub and remove the seal from the groove in the hub.

Inspection

Inspect the turbine and pump blades for looseness. Inspect all thrust surfaces for scores. Check the turbine splines for burrs and wear. Inspect the seal surface and front pump driving lugs for wear. Inspect the hub to pump mating surfaces

Fig. 32 Converter leak checking tool

Fig. 33 Converter leak checking tool installed with tire inflating chuck in drain hole

for scores. Inspect the stator thrust surfaces for scores and the stator splines for wear. Check the sprag assembly for worn or broken sprags and a broken or distorted spring. Inspect the stator inner and outer races for scores, Fig. 30.

Reassembly

Install the stator inner hub and snap ring. Turn the assembly over and install the outer race in the stator. Then install the sprag into the outer race, Fig. 31. Make sure the sprags are pointed in the correct direction.

Install the outer hub and snap ring. Insert the inner race replacer (tapered side first) into the sprag assembly while rotating the tool counterclockwise to position the sprags as shown in Fig. 31.

Install the inner race with the spline section up. Guide the tool with the hand while pushing the inner race into position. Check the stator for clockwise rotation while holding the inner race.

To assemble the pump, install a new seal on the pump hub and place the hub in the pump. Install the thrust washer into the hub of the converter pump.

To assemble the converter, install the stator with "Front" up. Install the thrust washer in the hub of the turbine. Retain the washer in place with transmission fluid. Install the turbine. Place the bronze thrust washer on the turbine hub. Install the converter cover, using a new gasket. Note position of cover and pump aligning marks. Install the cover to pump body attaching bolts and tighten them to 25-28 lbs. ft. torque.

Install On Transmission

Attach the converter housing to the transmission, tightening the bolts to 40-50 lbs. ft. torque. Install the converter into the housing, being sure not to rock the assembly as it is being installed otherwise the seal may be damaged.

Service Note

The torque converter on most 1958-60 and all 1961-63 vehicles is a sealed unit and cannot be serviced. There is, however, a procedure that makes it possible to determine prior to installation whether or not the unit is serviceable. The points that determine the serviceability of the converter and which may be checked without the use of special equipment are: Stator-to-impeller interference check; stator-to-turbine interference check; converter leak check. Also, the converter may be cleaned if it is suspected that it contains foreign material.

Converter Cleaning (Converter Out)

1. Place torque converter in upright position and pour two quarts of new clean solvent or kerosene into converter through pump drive hub.
2. Turn and shake torque converter so as to swirl the solvent through the internal parts. Turning the turbine and stator with the transmission input and reaction shafts will aid in dislodging foreign material.
3. Position converter in its normal operating position with one of the drain plugs at its lowest point. Remove the plug and drain the solvent. Rotate the turbine and stator and shake converter while draining to prevent dirt particles from settling. Repeat flushing operation at least once or as many times as required until solvent drained is clear.
4. Flush any remaining solvent in the converter with two quarts of new transmission fluid. Reinstall drain plugs and tighten to proper torque.

Stator-to-Impeller Interference Check

1. Position front pump on a bench with spline end of the stator shaft pointing up.
2. Mount converter on pump so that splines on one-way clutch inner race engage mating splines of stator support, and converter hub engages pump drive gear.
3. While holding pump stationary, try to rotate converter counterclockwise. The converter should rotate freely without any signs of interference or scraping within the assembly.
4. If there is an indication of scraping, the trailing edges of stator blades may be interfering with leading edges of impeller blades. In such cases replace converter.

Stator-to-Turbine Interference Check

1. Position converter front side down on bench.
2. Install proper front pump assembly to engage mating splines of stator support and stator and pump drive gear lugs.
3. Install input shaft, engaging splines with turbine hub.
4. While holding pump stationary, attempt to rotate turbine with input shaft. The turbine should rotate freely in both directions without any sign of interference or scraping noise.
5. If interference exists, stator front thrust washer may be worn, allowing stator to hit turbine. In such cases converter must be replaced.

Converter Leak Check

If there is an indication that the welds on the torque converter housing are leaking, the following check should be made before replacing the unit. A leak checking tool shown in Fig. 33 can be made out of standard parts and with minor adaptations will fit all cars.

1. Install tool in converter and expand it by tightening the wing nut. Attach the safety chains, Fig. 34.
2. Install air valve in drain plug threads.
3. Introduce air pressure into converter housing. Check pressure with tire gauge and adjust it to 20 psi. *Caution: Do not introduce pressure that is much greaer than 20 psi.*
4. Place converter in tank of water. Look for bubbles of escaping air. If no bubbles appear, it may be assumed that the welds are not leaking.

DESCRIPTION

In this transmission, two planetary units are used to give four forward speeds, Fig. 1. In each unit a hydraulically-operated clutch is used to lock two planetary members together for direct drive. Reduction (power multiplication) is obtained in both units by means of a band which can be used to hold one of the planetary units stationary. The bands are operated by means of hydraulically-controlled servos.

Oil for hydraulic operation is supplied by two oil pumps. The front pump is driven by the engine and the rear pump by the output shaft of the transmission.

NEUTRAL -- Both bands and clutches released.
1ST. SPEED -- Front & rear units -- in reduction.
2ND. SPEED -- Front unit in direct drive -- rear in reduction.
3RD. SPEED -- Front unit in reduction --- rear in direct drive
4TH. SPEED -- Front and rear units --- in direct drive.

Fig. 1 Band and clutch positions in different gears

Although both planetary units are similar, the rear unit differs in two ways from the front unit: It is longer, has more clutch plates and greater gear reduction; the rear servo is normally applied by spring pressure and released by oil pressure.

Clutch and Band Application

Fig. 2 shows the band and clutch application for all speeds. Bear in mind that in either planetary unit of the transmission (a) when the band is applied the clutch is disengaged and the unit is in reduction, (b) when the clutch is applied the band is disengaged and the unit is acting as a coupling for direct drive.

MAINTENANCE

Adding Fluid

1. Set hand brake and place selector lever in neutral.
2. Start engine and allow it to idle continuously for a minimum of two minutes to warm up the oil.
3. Remove and wipe dipstick and reinsert.
4. Add fluid as required to bring the level *exactly* to the FULL mark. Do not overfill the transmission as this will cause foaming which may result in improper operation. If the level is above the FULL mark, the excess should be drained.

Changing Fluid

Some models do not have a drain plug in the transmission oil pan; others do. In draining fluid from transmissions having an oil pan drain plug remove the flywheel inspection plate, the ⅛" pipe plug from the torus cover and the drain plug from the back of the oil pan.

On transmissions not having an oil pan drain plug, proceed as follows:

1. Remove flywheel inspection plate.
2. Remove $\frac{7}{16}$" hex head pipe plug from the torus cover and drain the fluid from the torus cover.
3. Center a drain pan directly below and as close as possible to the point where the external filler tube attaches to the transmission oil pan.
4. Hold the external fluid tube with a rag if the transmission oil is hot and carefully loosen nut attaching tube to oil pan.
5. As soon as nut is completely loosened, quickly rotate filler tube away from transmission so it will not interfere with fluid flow.
6. After draining install and tighten drain plugs.
7. Replace flywheel housing bottom cover.
8. Pour 9½ quarts of Automatic Transmission Fluid into transmission.
9. With selector lever in neutral, run

Fig. 2 Band and clutch application

engine at a fast idle for about 1½ minutes to fill the coupling.

10. Reduce engine speed to slow idle and check level. Then add fluid as required to bring level *exactly* to the FULL mark.

Caution

It is recommended that the oil pan and screen be removed and cleaned whenever the oil is changed. This is particularly important where the oil is drained by means of the filler tube since the opening is well above the bottom of the pan, thus allowing considerable quantity of old oil and contaminants to remain in the pan.

"In Truck" Repairs

AIR PRESSURE TESTS

Air pressure tests afford an excellent means of tracking down Hydra-Matic troubles. The only equipment needed is air delivered at about 80 lb. of pressure, and a special blow gun attachment which prevents air from escaping around the nozzle when it is applied to the transmission oil passages, Fig. 3.

Oil passages to be checked are identified in Fig. 4, and the passages should be checked in the sequence which follows. To gain access to the passages, drain the transmission, remove bottom pan, oil screen, side cover and control valve assembly.

Front Clutch Apply

Air pressure applied intermittently should move clutch piston audibly and actuate the front clutch. Fog of oil accompanied by rush of air from inside front unit drum indicates faulty front clutch seal. Leakage from other passages in side of case mean "short circuit" due to faulty transmission case or oil delivery tube.

Fig. 3 Checking passage in transmission with blow gun

Front Band Apply

Air pressure should actuate front servo and apply band without appreciable escape of air around flat surface of servo body. Small amount of blow-by is permissible from front band release passage.

Front Band Release

Air pressure will not actuate servo. Check for unusual escape of air between servo body and transmission case, and around band release cylinder.

Governor to 4-3 Valve

Slight click will be heard when overrun control valve is actuated. No leakage is permissible except for slight amount from front servo body and front band apply passage.

Rear Band Release

Air pressure should release rear servo and band. Small amount of air will escape past servo piston ring. Slight leakage is also permissible from compensator passage.

Rear Clutch Apply

Air pressure applied intermittently should move clutch piston audibly and actuate rear clutch. Other conditions described under Front Clutch Apply also apply here except check is made at rear unit drum.

Compensator to Servos

Air pressure should actuate rear servo to tighten rear band, and front servo to apply front band. Except for normal escape past piston ring gaps, no air leakage is permissible.

Main Line Pump Feed

Large amounts of air and oil will blow out from front side of front drum assembly. Any other leakage of air and oil indicates interconnected passages due to faulty transmission case.

Line Pressure

No leakage is permissible at any point when plug is sealed in place between band adjusting screws.

Valve Body Exhaust

Complete blow-by to interior of transmission case should result. Partial obstruction of passage can cause erratic shifting.

Reverse Clutch Apply

Intermittent application of air pressure should audibly actuate the reverse cone clutch piston. Unusual escape of air around the piston indicates leakage of oil seals in the reverse cone assembly.

EXTERNAL BAND ADJUSTMENT

If the special adjusting tool shown in Fig. 6 and a tachometer are not available, adjust bands by the internal method de-

Fig. 4 Identification of oil passages (typical)

Fig. 5 Trouble shooting chart

Fig. 6 Adjusting front band by external method

Fig. 7 Adjusting front band by internal method

scribed further on.

1. Set hand brake firmly and block wheels to prevent vehicle from moving forward during adjustment.
2. Start engine and allow it to run until temperature is normal (choke and fast idle off) before proceeding.
3. Connect tachometer to engine.
4. Place control lever in either 1-4 or 1-3 position.
5. Adjust carburetor idle screw to give 700 rpm.

Front Band

1. Remove floor pan and position band adjustment tool on front band adjusting screw, Fig. 6.
2. Loosen band adjusting screw lock nut. Then with special tool, Fig. 6, loosen band adjusting screw until engine speed increases to 900-1000 rpm (front drum spinning freely). *If engine speed does not increase to 900-1000 rpm, the bottom pan should be removed and the bands and drums inspected. If inspection shows bands and drums to be in good condition, adjust bands by the Internal Method. When adjusting bands with a new engine, speed may only increase to 800 rpm.*
3. Tighten band adjusting screw slowly until engine returns to 700 rpm (front drum now stopped).
4. Loosen band adjusting screw until engine speed increases, then tighten slowly until engine speed returns to 700 rpm. *The object of loosening and retightening the adjusting screw is to locate the exact point at which the band stops the drum from spinning. At this point wait 30 seconds. If engine speed increases, tighten screw 1/10 of a turn. Wait 30 seconds again and if engine speed increases, tighten screw 1/10 of a turn more. Repeat this procedure until engine speed remains at 700 rpm for at least 30 seconds.*
5. Set counter on tool to "00".
6. While holding adjusting screw lock nut stationary with long handle of tool, tighten adjusting screw exactly 6½ turns with short handle of tool (counter will read "6.5").
7. Hold adjusting screw stationary with short handle of tool while tightening lock nut with long handle.
8. Remove tool and tighten lock nut to 40-50 lb. ft. torque.

Rear Band

1. To adjust rear band, the tool shown in Fig. 6 is placed on the rear band adjusting screw. Repeat Steps 2 through 5 as performed under Front Band.
2. After counter on tool has been set to "00", position control lever in Neutral.
3. While holding lock nut stationary, tighten rear band adjusting screw exactly two turns (counter on tool will read "2.0").
4. Holding adjusting screw stationary, tighten lock nut.
5. Remove tool and tighten lock nut 40-50 lb. ft. torque.

INTERNAL BAND ADJUSTMENT

Before adjusting the bands, make sure the anchor of each band is seated on the adjusting screw and that the band is centered on the drum. Turn the output shaft and mainshaft by hand until band moves into operating position on drum.

Front Band

1. Remove pipe plug from top of front servo. Loosen hex adjusting screw of front servo gauge, Fig. 7, until approximately ⅛" of threads are exposed above gauge body. Install gauge in bore of servo body from which pipe plug was removed and *tighten gauge by hand only.*
2. Tighten hex adjusting screw of gauge with fingers until stem of gauge is felt to *just touch* piston in front servo. Do not over-tighten.
3. Using a wrench, tighten hex adjusting screw of gauge five complete turns.
4. Tighten front band adjusting screw until knurled washer on top of adjusting gauge is *just free* to turn.
5. Hold front band adjusting screw and tighten lock nut securely to 40-50 lb. ft. torque.
6. Loosen adjusting screw of gauge at

Fig. 9 Removing pressure regulator

Fig. 10 Layout of pressure regulator parts (½ ton models)

Fig. 8A Throttle lever position. Dimension "A" is measured in inches with lever back against its stop. Adjust by bending lever as required to obtain the dimension given below:

Chevrolet 1953-56	**3 9/16**
GMC	**3 9/16**

least five full turns and remove the gauge from the servo.

7. Install pipe plug in front servo body.

Rear Band

1. With band centered on drum, make sure rear servo actuating lever is not under tension. Position gauge shown in Fig. 8 on rear servo, with short leg hooked over end of accumulator body and long leg resting on servo piston stem.
2. Tighten rear band adjusting screw until rear servo actuating lever just contacts face of gauge. *If adjusting screw is turned beyond adjustment point, back screw out at least three full turns and repeat the adjustment.*
3. When correct adjustment is obtained, hold adjusting screw stationary and tighten lock nut to 40-50 lb. ft. torque.

THROTTLE LEVER, ADJUST

Whenever a transmission is overhauled or shifts are erratic, check the position of the throttle lever at the side of the transmission to see if it has become bent. This is a very important adjustment in that when the transmission throttle lever is all the way back against its stop the throttle valve in the carburetor must be fully closed. Gauges are available to measure the position of the throttle lever but if not available, use the data supplied in the caption under Fig. 8A.

After the lever has been bent to obtain the proper dimension, adjust the carburetor linkage as outlined in the truck chapters.

PRESSURE REGULATOR

While removing the pressure regulator from the side of the transmission, Fig. 9, unscrew the plug while holding hand against spring tension to avoid losing parts.

In disassembling the regulator, Fig. 10, do not remove the valve inner and outer cushions unless inspection shows necessity for replacement.

Inspect springs for weakness, collapsed coils and distortion. Inspect plugs for nicks and scores. Blow out all passages in regulator plug. Inspect regulator valve for nicks and scores, and make sure valve is clean. Clean all parts and wipe dry. Then reassemble the regulator.

Fig. 12 Transmission with side cover removed

Fig. 13 Layout of parking brake bracket parts

Fig. 15 Installation of G-2 plunger and bushing

Fig. 16 Removing governor oil delivery pipe

CONTROL VALVE

To remove the control valve, take off the oil pan and side pan. Disconnect the speedometer cable. Unfasten and remove the control valve by working toward front of case.

Extreme care must be used when handling the control valve assembly. Do not grip valve bodies in vise. Never use force when removing or installing valves or plugs.

The control valve should be laid flat on clean paper for disassembling. Keep component parts covered except parts on which work is being performed. Keep screws with correct part as valve body is disassembled.

Before inspection of valve bodies and plugs, make sure they are thoroughly cleaned and wiped dry. Then, referring to Fig. 11 as a guide, inspect the parts as follows:

1. Examine all valves and plugs to see that they are free of burrs, scores or other damage. Burrs may be removed with fine crocus cloth and light oil. Valves and plugs have sharp corners to prevent dirt from wedging between valves and plugs and valve bodies. *When removing burrs, do not round off sharp edges.*
2. With valves, plugs and valve bodies clean and dry, check each shifter valve, governor plug and regulator plug for free movement in their respective bores and operating positions. *It can be assumed that valves and plugs are free in their operating positions if they will fall of their own weight in their respective bores when valve body is shaken slightly.*
3. Check fit of throttle valve inside lever for looseness on throttle valve operating shaft.
4. Check inside detent control lever for looseness on manual shaft.
5. Make sure inside detent control lever pick-up pin is tight in place and not excessively worn.
6. Check for worn or damaged splines on manual shaft and throttle valve operating shaft.
7. Check action of throttle valve operating shaft in manual control shaft, and manual control shaft in hub of outer body.
8. If inspection shows levers and shafts bind, or loose and excessively worn, proceed as follows:
9. Support outer valve body and control shaft assembly so that throttle valve operating shaft, manual shaft and outer valve body will not be damaged during operating shaft pin removal.
10. Using a small punch and hammer, drive out pin.
11. Remove inside throttle valve lever, detent control lever, shaft seal and washer from outer valve body.
12. Replace damaged parts and reas-

Fig. 14 Layout of rear pump and governor parts

Fig. 17 Separating rear servo and oil transfer pipe

Fig. 18 Expoded view of front servo

semble to outer valve body.

13. While properly supporting outer valve body and control shaft, drive in new operating shaft pin. Check shafts for freedom of movement.
14. Check all springs for weakness and distortion.
15. Check all valve body, plate and cover contact surfaces for cracks or scores. Clean all passages. Check threads for crossed condition. Examine valve bodies for warpage by placing a straight edge across mating surfaces. If either valve body requires replacement, the complete control valve assembly must be replaced.
16. Inspect "T" oil ball check valve for damage or rough surface.

Reassembly

Lubricate each moving part with clean transmission fluid before part is installed. Refer to Fig. 11 for identification and location of parts. Assemble the parts in the outer valve body first, then the inner valve body.

When installing manual control valve in outer valve body make sure pick-up pin on inside detent control lever engages manual control valve correctly.

PARKING BRAKE BRACKET

After removing the control valve as outlined previously, remove the parking brake bracket by carefully sliding from the governor to avoid damage to oil rings, Fig. 12. If shims are present between case and parking brake bracket, the same shims must be reinstalled as long as the original transmission case is used.

Disassemble

1. While holding finger over parking blocker piston spring, use needle nose pliers to remove piston stop pin.
2. Remove blocker piston spring and use snap ring pliers to remove piston.
3. Clip off head of stop pin. Then while holding finger over reverse blocker piston spring, pull pin from brake bracket with needle nose pliers.
4. Remove reverse blocker piston spring and then pull piston out with snap ring pliers.

Inspection

1. Referring to Fig. 13, check springs for evidence of weakness, distortion and collapsed coils.
2. Check pistons and their bores for scores or burrs. Check freeness of pistons in their bores.
3. Make sure three ¼" plugs are securely staked in place in brake bracket.
4. Make sure all oil passages are clean.
5. Check four governor oil seal rings in bore of bracket; ring gap should be .001-.006".
6. Inspect bracket sleeve for scores or signs of extreme wear.
7. Inspect bracket for cracks or other damage.
8. See that crank operates freely in bracket without binding, yet shows no signs of unusual wear.
9. Check reverse shifter crank roller for wear. Check crank pin for cracks at point where pin joins crank.
10. Make sure lever return dowel pin is secure in brake lever.
11. Inspect pawl for wear or damage.
12. Clean all parts and wipe dry.

Assemble

1. Lubricate each moving part with transmission fluid before each part is installed.
2. Install reverse blocker piston (with slotted end exposed) and spring in bore of bracket. Compress spring with blunt screwdriver and install new stop pin. Peen ends of pin to hold in place.
3. Install parking blocker piston and spring in same manner and secure with stop pin.

GOVERNOR

After removing the control valve and parking brake bracket as outlined previously, use a file to mark the edge of the governor and drive flange so they may be reassembled in the same relative position. Then unfasten the governor from the flange and withdraw it from the case.

Refer to Fig. 14 when repairing the governor and inspect the parts as follows:

1. Inspect governor ring lands for wear; if lands are damaged or worn thin replace complete governor.
2. Inspect governor oil seal rings and for freedom in grooves of governor tower.
3. Inspect governor body for damage.
4. Inspect governor plungers for free movement. If G-1 plunger sticks, replace complete governor. If G-2 plunger sticks, replace this plunger and bushing.

When assembling the governor, insert the G-2 plunger with ear of bushing toward flat side of governor body. Body has slot on inside to accommodate ear of

Fig. 19 Exploded view of rear servo

Fig. 20 Compressing rear servo spring so unit can be taken apart

Fig. 21 Removing accumulator body and piston from servo body

Fig. 23 Rear servo oil passages

bushing. When properly assembled, end of bushing will be flush with bushing retainer side of governor body, Fig. 15. When attaching governor to drive flange, be sure to match the marks made on disassembly. When installed, be sure the governor does not bind; check by turning the output shaft while checking the governor in various positions.

Fig. 22 Disassembly of booster piston and spring and accumulator body

Fig. 24 Installing accumulator apply spring

REAR OIL PUMP & SERVOS

To remove the rear pump, take off the control valve and parking brake bracket and proceed as follows:

1. Back off band adjusting screws at least five turns.
2. Remove governor oil delivery pipe by prying gently with screwdriver, Fig. 16.
3. Remove rear pump and both servo attaching screws.
4. Separate front and rear servos at oil transfer pipe by moving rear servo toward rear of transmission, Fig. 17.
5. Remove rear servo.
6. Remove rear pump delivery pipe.
7. Remove front servo and front pump delivery pipe.
8. Position governor so large round counterweight is toward front of transmission.
9. Position one reverse drive flange attaching bolt so that no interference will be encountered when removing the rear pump and governor assembly from case. (If removing this assembly with transmission in car, position reverse bolt straight down; if transmission is out of car and inverted, attaching screw must be straight up.)

Rear Pump Repairs

Separate the pump cover from the body. Mark the outside of the pump driven gear with pencil or prussian blue so reassembly may be made in the original position.

Referring to Fig. 14, inspect pump gears for worn or damaged teeth. Inspect pump body for damage. Check mating surfaces of pump body for nicks or scores. Examine pump gear pocket for wear and scores. Check cover for scores or nicks, and check for warpage. Make sure rear oil pump intake pipe is not loose in pump body, and that the passageway in the pipe is not obstructed. Check for worn shaft and bushings by attempting to move shaft sideways in pump body.

Mount dial indicator on pump body to check drive flange runout. If runout, measured inside tapped holes, exceeds .002", the drive flange or complete pump must be replaced.

When assembling the pump, lubricate each part with automatic transmission fluid. Install pump driven gear in gear pocket with side previously marked facing up. Attach cover to pump body.

Front Servo Repairs

Refer to Fig. 18 when servicing this unit. When disassembled, inspect body for roughness, scoring, and for blocked or interconnected passages. Inspect release cylinder for scores. Inspect release piston and apply piston for scores, broken rings, freedom of rings in grooves, and see that oil passage is clear. Inspect springs for distortion.

Rear Servo Repairs

Disassemble this unit as shown in Figs. 20, 21 and 22. Then refer to Fig. 19 for identification and location of parts.

Fig. 25 Position of screwdriver for removal of reverse unit

Inspection

1. Referring to Fig. 19, inspect exhaust valve and its bore in accumulator body for scores. Check freedom of valve in bore.
2. Inspect servo body for scores, cracks or nicks. Using air pressure, check for interconnected or restricted passages, Fig. 23. Make sure two ¼"

Fig. 26 Removing reverse clutch internal gear and stationary cone

Fig. 27 Removing reverse piston-to-rear bearing retainer snap ring

Fig. 28 Removing reverse clutch piston

plugs are tight in servo body.

3. Check rear band actuating lever for free operation, worn socket, or excessive wear at actuating pin.
4. Make sure oil rings are not broken. Check ring gap and freedom of rings in piston grooves.
5. Check booster spring for scores. Make sure ring grooves of piston are clean. Check booster piston stem for looseness.
6. Inspect accumulator piston for scores. Check piston stem for looseness and obstructed passage. Make sure ring groove is clean.
7. Check all springs for weakness, collapsed coils or distortion.
8. Inspect accumulator body for scores or obstructed passages. Make sure check valve is not broken or rivet loose. Be certain check valve plunger is free. See that hole in check valve is open and that valve seats flat on accumulator body.
9. Clean parts and wipe dry.

Reassembly

1. Parts should be lubricated with transmission fluid unless otherwise specified.
2. Position servo actuating lever flat on bench. All parts used in this step must be dry. Install pin and 18 needle bearings in lever. Carefully withdraw pin. While pressing downward with thumb on needle bearings, rotate thumb and lever in opposite directions. Needle bearings will lock in place.
3. Position rear band actuating lever in bracket of servo body and install clevis pin. Secure clevis pin with cotter pin.
4. Install oil rings in grooves of pistons.
5. Compress oil ring and install accumulator piston in its body.
6. With accumulator piston seated on soft block of wood, position tapered end of accumulator apply spring over stem of piston. Tap spring into groove of stem with plastic hammer, Fig. 24.
7. Install spring in booster piston, being sure spring fits against bottom of piston.
8. Install booster piston and spring in accumulator body.
9. Install exhaust valve and spring in accumulator body.
10. Position new gasket on accumulator body.
11. Compress booster piston oil ring, then install servo body over accumulator and piston assembly, lining up bosses of both bodies. Guide stem of booster piston through small hole in servo body.
12. Place assembly in spring compressor, Fig. 20. After assembly, tighten spring retainer bolts to 10-13 lb. ft.
13. Test operation of servo by applying air pressure in rear band release passage, Fig. 23.

REVERSE UNIT

Before the reverse unit can be removed, it is necessary to remove the oil pan, side cover, control valve, parking brake bracket, governor, front and rear servos and rear pump. How these units are removed has been outlined previously.

Remove the six reverse drive flange attaching cap screws; the drive flange can be held from turning by using a hammer handle as a lever on the rear band strut.

Insert a screwdriver or a suitable spacer, Fig. 25, between the center bearing cap and rear clutch drum to prevent the drum from moving forward. This will prevent the forward clutch plate from dropping off the front end of the rear clutch hub. Should this happen the transmission will have to be removed to replace it.

Fig. 29 Installation of thrust washers

Fig. 30 Installation of reverse internal gear and stationary cone

Unfasten the rear bearing retainer from the transmission and withdraw the retainer and reverse unit from the mainshaft. Take out the reverse clutch stationary cone key to prevent its loss, Fig. 25.

Disassembly

1. Remove speedometer driven gear and sleeve from rear bearing retainer.
2. Remove snap ring from output shaft. Remove output shaft.
3. Compress reverse stationary cone with hands and lift off internal gear and clutch cone, Fig. 26.
4. Remove snap ring and bearing from bearing retainer.
5. Mount bearing retainer in compressor tool shown in Fig. 27, and remove the large snap ring.
6. Remove the tool and take out the release spring retainer washer and six piston release springs.
7. Remove clutch piston from bearing retainer by lifting straight out. *It*

may be necessary to apply air pressure behind piston to aid in removal. If so, apply the pressure to small hole "A", Fig. 28.

8. Remove piston outer oil seal from piston and inner oil seal from hub of rear bearing retainer.
9. Remove large bronze thrust washer from internal gear or bearing retainer.
10. Use snap ring pliers to expand clutch stationary cone and remove cone from internal gear.
11. Remove clutch release spring retainer and release (wave) spring from internal gear by rotating to the left to release retaining lugs.
12. Remove planet carrier snap ring.
13. Lift planet carrier from output shaft.
14. Remove planet carrier locating snap ring from output shaft.
15. Lift center gear and flange from output shaft.
16. Remove center gear steel and bronze thrust washers from shaft.

Inspection

1. Inspect all parts for nicks, burrs, scores, excessive wear or other damage. Check springs for weakness or distortion.
2. See that rear oil pump drive gear is tight on carrier and that pump drive gear ball is in place. If gap in snap ring is not over ball, move snap ring around to where ball can be seen.
3. Inspect reverse center gear and flange for damaged teeth or worn bushing. Gear is not furnished separately; if necessary, replace gear and flange. Position flange on rear planetary unit internal gear and check for distortion.
4. Check fit of key in cone slot.
5. Make sure oil passages in rear bearing retainer are open.
6. Clean all parts and wipe dry.

Reassembly

1. Install thrust washers in drive flange recess as shown in Fig. 29.
2. Insert output shaft through drive flange and center gear until planet carrier bottoms on the two thrust washers.
3. Keep thrust washers from moving and set output shaft on bench with carrier end down.
4. Install planet carrier-to-output shaft snap ring.
5. Install planet carrier over output shaft with rear oil pump drive gear down, meshing pinions with center gear. Be sure assembly is bottomed against planet carrier snap ring.
6. Install snap ring in groove above planet carrier on output shaft.
7. Install clutch stationary cone on internal gear cone, using snap ring pliers to spread stationary cone for installation.
8. Position bronze internal gear thrust washer over collar of internal gear, retaining with grease.
9. Install clutch release (wave) spring and spring retainer on internal gear side of reverse internal gear. Open ends of spring must be down against internal gear and midway between two of three locating holes. Depress retainer and twist clockwise to engage lugs.
10. Install clutch piston inner seal with lip down in seal groove of rear bearing retainer hub.
11. Position piston inner seal by inserting clutch piston into bore of bearing retainer. Then remove clutch piston.
12. Install piston outer seal in groove of reverse piston with lip of seal toward flat side of piston.
13. Install reverse piston in rear bearing retainer. Because of interference between ledge inside rear bearing retainer and piston outer seal a suitable sleeve or Tool J-4752 must be used to install the piston. After installation, run a .010" feeler around the piston to make sure the outer seal is properly positioned.
14. Insert six clutch piston release springs in their bores of clutch piston.
15. Position release spring retainer on release springs and lay snap ring in position. Then compress springs with tool shown in Fig. 27.
16. Remove compressor tool and install internal gear and stationary cone in rear bearing retainer as follows: While compressing clutch stationary cone with the hands as shown in Fig. 26, install gear and cone in bearing retainer. Position keyway of cone so it will line up with keyway in transmission case, Fig. 30.
17. Install output shaft to rear bearing retainer, meshing teeth of planet carrier with teeth of internal gear.
18. Install output shaft bearing and the two snap rings in rear bearing retainer.
19. Install speedometer driven gear.
20. Stick a new gasket on rear bearing retainer with grease.
21. Place key in keyway of stationary cone, retaining with grease.

Repairs Requiring Transmission Removal

TRANSMISSION, DISASSEMBLE

1. Strip the fluid coupling parts from the mainshaft. Remove the torus cover by working neck of cover gently over oil seal; then pull cover out with a quick jerk, Fig. 31.
2. With torus members removed, remove driven torus snap ring from mainshaft.
3. Remove control valve, parking brake bracket, front and rear servos, rear oil pump, governor and pressure regulator as outlined previously.
4. At this time the mainshaft end play should be checked to determine the correct size selective thickness thrust washer to be used when reassembling the transmission. Mount a dial indicator as shown in Fig. 32 and move the mainshaft back and forth while holding the mainshaft end play guide with a screwdriver as shown. Correct end play should be .004-.015". Do not force mainshaft as this will produce an inaccurate reading. *If end play is not within specified limits, record the amount of end play so the proper thickness washer can be installed when the transmission is reassembled.*

Fig. 32 Checking mainshaft end play

5. Remove intermediate shaft snap ring and steel and bronze thrust washers from planet carrier shaft.
6. Remove front pump locating washer, Fig. 33.
7. Unfasten and remove front pump, Fig. 34.
8. Remove front drive gear rear thrust washer (bronze) from front planet carrier shaft.
9. Remove reverse unit as outlined previously.
10. Install rear hub retainer tool, Fig. 35, on rear unit drum.
11. Remove two center bearing cap bolts and lock plate. Then lift front and rear planetary units from case.
12. Remove rear clutch hub rear snap ring.
13. Lift rear unit from shaft.
14. Remove center bearing cap from oil delivery sleeve.
15. Remove rear clutch hub washer and snap ring.
16. Slide oil delivery sleeve off shaft.
17. While holding snap ring pliers in one hand and using the other hand to guide snap ring, remove ring from shaft, Fig. 36.

Fig. 31 Exploded view of transmission

Fig. 33 Removing front pump locating washer

FRONT PUMP REPAIRS

Disassemble, Fig. 37

1. Remove pump from drive gear.
2. Separate cover from body.
3. Lift body from cover.
4. Press valve guide with blunt screwdriver and slip retaining pin from body.
5. Remove pump relief valve and related parts.
6. Remove intake pipe oil seal.
7. Mark outer face of rotor with pencil or prussian blue so it will be installed in same relative position.
8. Remove remaining parts from body and cover.
9. With a chisel, remove oil seal from cover and discard seal.

Fig. 34 Removing front pump and drive gear

Fig. 35 Rear hub retainer tool in position

Inspection

1. Referring to Fig. 37, check pump slide bleed holes for dirt or restrictions. A piece of tag wire should be pushed through holes to make sure they are open.
2. Make sure slide is free in pump cover. Examine slide for nicks, scores or excessive wear.
3. Examine vanes for scores, burrs or nicks. Vanes will have a distinct polished wear pattern on side bearing against slide. Check vanes in slot of rotor for freeness.
4. Check pressure regulator valve in its bore for freeness.
5. Check freedom of pump relief valve in its bore. Check relief valve for nicks or burrs.
6. Check oil seal ring in groove of pump cover for freeness. Make sure ring is not broken. Check ring gap.
7. Inspect pump bushing for scores or flaking. Slight wear is permissible.
8. Check keyway in rotor for burrs or wear. Inspect all rotor contact surfaces for wear, burrs or nicks.
9. Make sure all passageways are free of restrictions.
10. Inspect pump body and cover for cracks or damage. Make sure the two dowel pins in cover are not loose. Check mating surfaces of body and cover for nicks or scores.
11. Examine body and cover slide contact surfaces for nicks or burrs.
12. Check all springs for weakness or distortion.
13. Inspect front drive gear for damaged teeth, worn bushings, or scored contact surfaces.
14. Inspect drive gear key and keyway in gear for wear or burrs.
15. Clean all parts and wipe dry.

Reassembly

1. Lubricate each moving part with transmission fluid before part is installed.
2. Install relief valve parts.
3. Insert new intake pipe oil seal in body.
4. Install priming springs and slide in cover.
5. Install on vane ring. Then install rotor in cover with previously marked face of rotor up.
6. Install seven pump vanes in slots of rotor. Be sure vanes fit between *vane ring and slide. Inspect vanes for wear pattern. One edge of vane will be polished for its entire length; this edge should face slide. The opposite edge will be polished only where it contacts vane rings.*
7. Center rotor in slide and install second vane ring.
8. Check with feeler gauge between vane and slide. With vanes contacting slide on one side, clearance should not exceed .003″ on opposite side. If clearance is excessive, replace pump.
9. Assemble body to cover and tighten attaching bolts to 12-15 lb. ft. torque.
10. Move rotor by hand to make sure rotor, vanes and slide move freely. After compressing priming spring, make sure it will return slide after spring is released.
11. Install new oil seal ring in groove of cover. Then install new front cover oil seal (step side up) in cover. Lubricate rubber and felt portions of oil seal before installing.
12. Apply sealing compound (Permatex No. 3) around edge of oil seal and cover.
13. Assemble pump on drive gear, being sure they assemble freely.

OIL DELIVERY SLEEVE

1. Examine oil delivery sleeve for scored bearing surface.
2. Inspect oil seal ring grooves to see that they are clean and not damaged. Check for freedom of rings in sleeve grooves.
3. Insert paper clip, Fig. 38, through both oil holes to see that passages are open. End of paper clip must protrude through passage as illustrated.
4. Test oil delivery sleeve for leaks as follows: Position sleeve in case with dowel hole toward case. Install center bearing cap with dowel in one of the two oil holes. Install and tighten center bearing cap bolts. Make sure sleeve is tight and cannot be rocked. *If sleeve can be rocked, a new sleeve must be installed. If the new sleeve can be rocked, transmission case must be replaced since center bearing cap is sold only with matched transmission case.*
5. Apply transmission fluid on each side of center bearing cap. Using a blow gun (J-4353-1) connected to a source of air pressure, apply pressure to each of clutch holes, Fig. 39, in side of transmission case.
6. If leakage is indicated, attempt correction by installing new oil delivery sleeve. If the new sleeve leaks, dress the center bearing cap down with fine emery cloth on a surface plate. Repeat test and if sleeve still leaks. replace transmission case.
7. Remove sleeve from case.

Fig. 36 Removing front unit rear snap ring

Fig. 37 Layout of front pump parts

Fig. 38 Checking passages in oil delivery sleeve

Fig. 40 Removing clutch drum snap ring

Fig. 42 Seating rear clutch drum against snap ring

Fig. 39 Clutch oil passage identification

Fig. 41 Seating front clutch drum against snap ring

Fig. 43 Installing clutch hub by rotating parts as shown by arrows

BAND INSPECTION

1. Do not pry either band open or distort in any way. Bands are surface ground at the factory for drum fit.
2. Inspect both bands for burned or worn linings or loose rivets. If face of linings are worn down to bottom of grooves, replace band and lining assemblies.
3. Inspect steel bands for cracks or distortion.
4. Check strut on rear band for alignment and free pivoting.
5. Inspect anchor ends of front band for broken welds or worn sockets.
6. Inspect rear band release spring for weakness, distortion or collapsed coils.

FRONT PLANETARY UNIT

Disassembly

1. Remove clutch drum snap ring, Fig. 40.
2. Remove clutch drum with piston from front unit drum by tapping sun gear.
3. Remove inner and outer clutch release springs from front unit drum.
4. Remove clutch plates as a unit.
5. Hold clutch drum in hand and tap sun gear around its face to remove clutch piston, Fig. 41.
6. With blunt screwdriver, remove large clutch piston seal and expander from piston and small seal with expander from clutch drum. Discard seals and expanders.

Inspection

1. Inspect clutch drive pins for scoring, looseness or distortion. Replace drum assembly if any of these conditions are found. Pins are not furnished separately.
2. Inspect drum for deep grooves, scores or cracks at band or clutch plate surfaces.
3. Inspect clutch springs for weakness, collapsed coils or distortion. *Slight wear (bright) spots on side of outer springs, indicating slight contact with drum is permissible.*
4. Removing one clutch plate at a time, inspect steel plates for scored surfaces. Inspect composition plates for roughness or damage. If flakes of facing can be removed by scratching by thumb nail, plate must be replaced. Discoloration, however, is not an indication of failure.
5. Inspect clutch piston for scores, cracks or distortion. Make sure oil seal groove is clean.
6. Examine front clutch drum for scores in piston bore and oil delivery sleeve bore. Be sure oil seal groove is clean. Inspect gear teeth and thrust faces. Inspect clutch drum bushings for wear.

Fig. 44 Assembling front planet carrier, front drum and plates by rotating parts as shown by arrows

Fig. 45 Installing thrust washers on intermediate shaft

7. Inspect planet carrier pinion gears for damaged teeth and excessive roller bearing wear. Inspect bearing surface of planet carrier (intermediate) shaft, which contacts torus check valve, for roughness or nicks. Smooth off with a stone if this condition exists.
8. Check thrust washers for wear or scores.
9. Clean all parts and wipe dry.

Reassembly

1. Position planet carrier in holding fixture (J-2187) with clutch hub up.
2. Apply transmission fluid to both sides of clutch plates. Starting with a composition plate, install composition and steel plates alternately. Install steel plates with square notches over clutch drive pins.
3. Position front unit drum with drive pins up over hub of carrier and resting on pinion gears.
4. Install six outer clutch release springs through plates into spring holes of drum. Install six inner springs in outer springs.
5. Position new inner rubber seal on clutch drum above seal groove. Install new brass expander into seal groove with expanding lips down.
6. While holding brass expander in position with fingers, work new inner piston rubber seal into groove with lip down over brass expander. *Work expander well back under seal so brass edges are not exposed.*
7. Install clutch piston in drum to insure proper positioning of inner seal and expander. Then remove piston from drum.
8. Apply a small amount of transmission fluid to new large rubber piston seal.
9. Insert new large brass expander in groove in piston, with expanding lips toward flat surface of piston. Hold expander in place with thumb over ends of expander.
10. While holding piston and expander, insert new large rubber seal in piston groove with lip toward flat side of piston. Start seal into groove a short distance from point where thumb is holding expander ends. Work seal into groove toward thumb until seal is over expander ends. Then gradually work remainder of seal into groove.
11. Install piston in clutch drum. Apply hand pressure to face of piston and start seal into drum, using a smooth screwdriver in a wiping action. Rotate piston until it bottoms in drum and square notches in piston are aligned with holes in drum.
12. With sun gear down, install clutch drum and piston over planet carrier and into front drum, engaging release springs in pockets of clutch piston.
13. Lift unit from carrier and position in arbor press and apply only enough pressure to install snap ring. Position snap ring gap halfway between two of the drive pins.
14. Remove unit from press and tap sun gear to seat drum against snap ring, Fig. 41.

REAR PLANETARY UNIT

1. Remove clutch hub retainer bracket (Tool J-2174) from rear unit drum.
2. Remove clutch hub and thrust washer.
3. With rear unit in press as for front unit, remove snap ring.
4. Separate clutch drum from rear unit drum by tapping lightly on clutch drum rear thrust face.
5. Remove clutch release springs and guide pins from rear unit drum.
6. Remove clutch plates as a unit.
7. Hold clutch drum in hand and tap against inner hub of drum to remove clutch piston.

Inspection & Reassembly

Inspect this assembly in the same manner outlined for the front unit. Reassemble the unit in the reverse order of disassembly, following the same procedure for installing clutch piston seals as outlined for the front unit clutch.

Seat the rear clutch drum against the snap ring as illustrated in Fig. 42. After the clutch hub and thrust washer is installed into the clutch drive plates, rotate the hub and drum in opposite directions to mesh splines of hub with teeth of plates, Fig. 43. When properly installed, clutch hub should be flush or slightly below counterbore in drum.

Install rear clutch hub retainer bracket (tool J-2174) on rear unit to hold clutch hub in place (see Fig. 35).

Fig. 46 Installation of oil delivery sleeve

Fig. 47 Installing front and rear units

TRANSMISSION CASE INSPECTION

After cleaning transmission case, inspect for cracks, stripped threads, nicks and burrs. Poke a piece of 1/8" welding rod through all passages to remove any restrictions. Apply air pressure to all passages.

If band adjusting screw threads are stripped, transmission case must be replaced. Never tap oversize threads and insert oversize adjusting screws as it will be impossible to make proper external band adjustments.

TRANSMISSION, ASSEMBLE

1. Mount transmission case upside down in holding fixture.
2. Install front and rear band adjusting screws and lock nuts.
3. Install pressure take-off pipe plug in hole located between band adjusting screws. Tighten plug to 15-18 lb. ft. torque.

Assemble Planetary Units to Front Planet Carrier

1. Insert front carrier into front unit drum and clutch drive plates. Rotate carrier while working into position in front drum, Fig. 44.
2. Position carrier in holding fixture (J-2187).
3. Install thrust washers as shown in Fig. 45. Locating lug of steel thrust washer must fit over flat of intermediate shaft.
4. Position new locating snap ring on bench with tapered points up. With snap ring pliers held vertically, engage points of ring. While guiding ring with one hand, slide ring downward over intermediate shaft and

Fig. 48 Installing mainshaft in output shaft

into groove of shaft above steel thrust washer.

5. Position oil delivery sleeve on intermediate shaft of front planet carrier. Oil rings nearest end of sleeve must be down into front planetary unit.
6. Compress lower set of oil rings with compressor tool, Fig. 46. Tap sleeve until it bottoms in bore of front unit drum.
7. Install rear clutch hub snap ring in groove of planet carrier intermediate shaft. Then install snap ring spacer.
8. With compressor tool, compress exposed oil delivery sleeve rings. Latch handles of compressor securely.
9. Place rear planetary unit over intermediate shaft until it bottoms on compressor tool. Keeping rings compressed with tool, release handle latch and, while slightly releasing pressure on tool, push rear unit downward on oil delivery sleeve.
10. Remove compressor tool and install rear clutch hub rear snap ring.
11. Make sure both drums rotate with slight force. If either drum binds, disassemble the unit to correct cause of trouble.

Install Front & Rear Planetary Units

1. Position center bearing cap on oil delivery sleeve with dowel registered in dowel hole. *Cast taper on bearing cap should be toward front unit.*

Fig. 49 Checking governor tower runout

2. Position front band over drum so short anchor end will fit over band adjusting screw when units are placed in case. Install suitable wire or spring to hold band on drum.
3. Guide planetary units in case as shown in Fig. 47.
4. Remove spring or wire from band and position anchor end of front band on adjusting screw.
5. Install rear band on drum so anchor end of band rests on adjusting screw.
6. Install new center bearing cap lock plate and attaching bolts, tightening bolts only finger tight.
7. Apply air pressure through each of the clutch passage holes in case. Listen for sound of clutch application.
8. Install large screwdriver between center bearing cap and rear clutch drum to prevent rear drum from moving forward.
9. Remove clutch hub retainer bracket (J-2174) from rear unit drum.
10. Coat rear clutch hub rear thrust washer with grease and stick it in the counterbore of rear clutch hub.

Install Reverse Unit & Mainshaft

1. If shaft did not have correct end play prior to disassembly, select proper size selective washer to obtain .004″ to .015″ end play. Eight sizes of thrust washers are available for this purpose.
2. Stick the correct size thrust washer in counterbore of output shaft with grease.
3. Insert mainshaft into output shaft, meshing center gear of mainshaft with planet pinions of output shaft, Fig. 48.
4. Insert mainshaft, output shaft and reverse unit through rear of case, guiding mainshaft through intermediate shaft of front planet carrier. Align stationary cone lock key with keyway in case and rear bearing retainer bolt holes with holes in case. *Rear bearing retainer will not fit tightly against case at this point.*
5. Just start five rear bearing retainer attaching bolts and parking brake pawl support bolt and lock.
6. Rotate mainshaft to align holes in reverse drive flange and rear unit drum, then install six attaching bolts and washers. After two of the bolts are centered finger tight, remove the wedging screwdriver. While holding drum with tool J-1459, tighten bolts to 10-13 lb. ft. torque. *Do not torque parking brake pawl support bolt at this time*
7. Test for freeness by turning mainshaft, output shaft and both drums.
8. On ¾ and 1 ton trucks, install new output shaft bearing oil seal in rear bearing retainer. Lubricate rubber and felt portions of seal before installation. Apply sealing compound (Permatex No. 3) to edge of seal and rear bearing retainer.
9. On all models, slide front universal joint yoke spacer and yoke on output shaft. Position yoke washer in counterbore of yoke and stake

Fig. 50 Checking governor drive flange runout

Fig. 51 Installing front servo

Fig. 52 Installing parking brake pawl support bolt and lock

Fig. 53 Installation of reverse oil pipe

Fig. 54 Aligning governor

washer in place. Install special hex head bolt in bore of output shaft.

Install Front Oil Pump

1. Position thrust washer over intermediate shaft against shoulder of front planet carrier.
2. Install new "O" ring seal over front pump body and against pump cover.
3. Position front oil pump and drive gear over intermediate shaft, aligning locating washer counterbore in pump cover with counterbore in transmission case.
4. Install washer in counterbore of pump cover and case.
5. Install pump cover attaching bolts and tighten to 10-13 lb. ft. torque.
6. Install bronze and then steel thrust washers over intermediate shaft and against front end of front drive gear.
7. Install snap ring in groove of intermediate shaft, immediately forward of the two thrust washers just installed.
8. Tighten center bearing cap bolts evenly to 40-50 lb. ft. torque. Using large pliers, bend lock plate edges up against flats at bolt heads.

Mainshaft End Play

Mainshaft end play should be checked at this time before proceeding with the assembly of the transmission. Check end play as previously described when transmission was disassembled.

Install driven torus snap ring in groove of mainshaft.

Install Rear Oil Pump & Governor

1. Position large round governor weight toward front of case and locate one of reverse drive flange attaching bolts up. This will provide clearance for pump and governor to be installed.
2. Install pump and governor, rotating governor to mesh driven gear with bronze drive gear. Attach pump to case and tighten bolts to 15-18 lb. ft. torque.
3. Install rear pump discharge pipe into passage of pump.

Checking Governor & Drive Flange Runout

1. Mount dial indicator as shown in Fig. 49 and check runout of governor tower. Rotate output shaft several revolutions and note reading. If runout exceeds .005", remove governor from drive flange and reinstall it 180° from original position and recheck runout.
2. If runout still exceeds .005", remove governor from drive flange and mount dial indicator as shown in Fig. 50.
3. Rotate output shaft several revolutions and if drive flange runout is less than .002", install a new governor. If runout exceeds .002", correct the condition by installing one or all of the following parts: Governor drive flange, gear set, or complete rear oil pump assembly.

Install Front & Rear Servos

1. Loosen but do not remove two front oil pump attaching bolts.
2. Insert front pump delivery pipe in front pump.
3. Position front servo with piston stem in slot on end of front band and front oil pump delivery pipe aligned with passage in servo body.
4. While holding front servo, align rear oil pump discharge pipe with passage in front servo valve body, Fig. 51.
5. Move front servo toward position on case while guiding front pump delivery pipe and rear pump discharge pipe into proper passages in front servo.
6. Just start (2 or 3 threads) two front servo attaching bolts and washers.
7. Rotate rear band until ends of band are exposed. Install rear band release spring in recess in end of band and over guide pin on rear band strut. Turn band until its end is against band adjusting screw.
8. Place rear servo in position, engaging rear band strut with actuating lever of servo and, while raising front servo slightly, enter oil transfer pipe from front servo into rear servo. Then push both servos into position on transmission case.
9. Enter two rear servo attaching bolts and washers. Then tighten front and rear servo attaching bolts to 23-28 lb. ft. torque.
10. Retighten the two previously loosened front oil pump attaching bolts to 10-13 lb. ft. torque.

Install Oil Pressure Regulator

Install pressure regulator in transmission case and tighten regulator valve plug to 40-50 lb. ft. torque.

Install Parking Brake & Control Valve

1. Remove parking brake pawl support bolt from rear bearing retainer.
2. Position brake pawl in case as far down as it will go.
3. Position gaps in oil rings on governor tower up to facilitate installation. Place chamfered side of brake bracket oil delivery sleeve over end of governor tower. Press brake bracket gently into position, guiding oil rings on governor tower into oil delivery sleeve of brake bracket.
4. Install reverse shifter crank roller on brake pawl crank. Raise pawl to position and install pawl support bolt and bolt lock to transmission case, Fig. 52. Tighten bolt to 23-28 lb. ft. torque.
5. Bend one lip of lock against bolt and two lips against rear bearing retainer.
6. Install parking brake bracket attaching bolts, blocker piston stop pin retainer and lock washer. Do not tighten bolts. Leave brake bracket ⅛" away from transmission case. *Be sure to install blocker piston stop pin retainer on bottom bolt. This retainer keeps parking blocker stop pin in place, seals against oil pressure leaking through bolt hole and locks bracket-to-case bolt in place.*
7. Install reverse clutch oil pipe with "L" end in transmission case.
8. Install two oil delivery pipes in parking brake bracket.
9. Position pawl return spring over inside governor oil delivery pipe, then hook other end of spring over brake lever pin.
10. Install control valve and start four attaching bolts. Press control valve and brake bracket against case and tighten valve attaching bolts to 6-8 lb. ft. torque.
11. Insert short end of pressure regulator reverse oil pipe into bore of control valve and long end of pipe into case, Fig. 53.
12. Loosen two rear oil pump attaching

bolts. Position governor aligning tool, Fig. 54.

13. Tighten rear oil pump bolts and brake bracket to 15-18 lb. ft. torque.
14. Rotate tool. Turn mainshaft to rotate governor, which should turn freely. Turn mainshaft to turn governor ¼ turn. Recheck governor and tool for freeness. If governor or tool bind at any point, loosen parking brake bracket and/or rear oil pump and reposition to give freedom to governor. Recheck governor each ¼ turn for a complete revolution.
15. Remove governor aligning tool.
16. Install governor oil delivery pipe.
17. Turn mainshaft to rotate governor one full turn. Make sure governor weights do not strike oil delivery pipe. Pipe should have correct bend to provide clearance for governor weights in their outward positions.

Final Assembly

Adjust bands as outlined elsewhere in this section. Then install side cover, oil pan and screen. Move transmission outer shift lever to neutral position. Install oil breather and indicator in case.

MODEL INDEX & ENGINE APPLICATION

ENGINE IDENTIFICATION—Autocar Service Parts Identification Plate is located inside of truck cab. Stamped on the plate is the model of the engine, transmission, auxiliary transmission, rear axle and front axle. This data represents only the equipment on the vehicle when it was shipped from the factory. Prior to Autocar's assimilation by The White Motor Company, identification plates were attached to engines and transmissions.

CYLINDER HEAD, REPLACE

Autocar Engines

A new cylinder head gasket should be installed whenever the cylinder head has been removed for any reason. When installing the head, draw the nuts down evenly and in the order shown in Figs. 1 and 2, using the chart that matches the head being worked on. Tighten the nuts gradually, repeating the operation several times and in the proper order. After 500 miles of operation, again check the tension of the nuts and torque them to the values given in the *Tune Up & Valve Specifications* table.

Autocar 377 engine

Le Roi Engine

To remove the head or heads, drain the cooling system and remove manifolds, valve cover and oil line. Remove the rocker shaft assembly and, after removing the nuts from the studs, lift off the head or heads.

To install the heads, first tighten the stud nuts *finger tight.* Replace the intake manifold between the heads and level it so that each side will have equal projections of gaskets above and below the manifold flange.

Install the exhaust manifolds, center them on the studs and tighten the stud nuts and clamp nuts *finger tight.*

Tighten the head nuts to approximately 30 lb. ft. temporarily. Then tighten the manifold nuts approximately 20 lb. ft. temporarily. Finally, tighten both head and manifold nuts to the final torque in the sequence shown in Fig. 3. Final torque is 90 lb. ft. for cylinder heads and 60 lb. ft. for manifolds.

Check the intake manifold alignment by sliding a thin feeler gauge around the flanges. The mating flange contact should be such that the feeler gauge cannot slide under the manifold.

Rotate the engine by hand to see that the push rods do not touch the cylinder head at any time. If this does happen, loosen and realign the head.

ROCKER ARM SERVICE

Le Roi Engines

Sludge and gum formation in the rocker arms and shafts will restrict the normal flow of oil to the rocker arms and valves. Each time the assemblies are removed they should be disassembled and thoroughly cleaned.

After disassembling, clean all gum and sludge formation from the inside and outside of the shafts and rocker arms. Check the fit of the rocker arms on the shafts and the valve end of the rocker arms for excessive wear. If the rocker arm radius is grooved on the valve end, replace the part.

Fig. 1 Cylinder head tightening. Autocar 377 engine

Fig. 2 Cylinder head tightening. Autocar 447 and 501 engines

Check each push rod for a bent or damaged condition. If bent more than .020″ when checked with a dial indicator, replace the push rod. Do not attempt to straighten a bent push rod. If a dial gauge is not available, at least check the rod for straightness by rolling it on a perfectly flat surface plate.

Cement the new rocker arm cover gasket to the cylinder head instead of to the cover. When the gasket is cemented to the cover, it is more easily damaged when removing or installing the cover.

VALVES, ADJUST

All Engines

On Le Roi engines, before adjusting the valves, the engine must be thoroughly warmed up for about 30 minutes to stabilize the expansion of all parts. The valves may then be adjusted with the engine not running.

On Autocar engines, the valves may be adjusted with the engine cold or at shop temperature.

Turn the engine over by hand to bring No. 1 piston up on its compression stroke and to its firing position. Then adjust the valves of this cylinder. Turn the engine over to the next cylinder in the firing order and adjust the valves in this cylinder. Adjust the remaining valves by following the firing order of the engine being serviced. (Fig. 4 shows the cylinder numbering system and firing order of Le Roi engines.)

Autocar 447 and 501 engines

VALVES, REMOVE

Autocar Engines

After taking off the cylinder head, remove the valve chamber covers. With a suitable valve spring compressor, raise the springs on those valves which are closed and remove the valve locks. Then turn the crankshaft until those valves which are open are closed and remove the remaining valve locks.

Remove all valves and place them in a board with numbered holes so that they can be identified as to the valve port from which they were removed.

Le Roi Engines

After removing the cylinder head (or heads), withdraw the push rods and tag or otherwise locate them so they may be returned to their original position.

Place the head on the workbench with a block of wood under each combustion chamber in turn to hold the valves closed while removing the valve locks.

With a suitable spring compressor, compress the valve spring until the lock retainer can be removed. Remove the valve lock and valve rotator, spring and washer. After removing all valves and related parts, tag or otherwise locate them so they may be returned to their original position.

Fig. 4 Cylinder designation plate. Le Roi engine

Le Roi H540 engine

Le Roi H540 engine

VALVES, GRIND

All Engines

In refacing valves, take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced.

Inspect the valve seats in the block or head for cracks, burns, pitting, ridges or improper angle. During any general engine overhaul it is advisable to reface the valve seats regardless of their condition. If new valve guides are required, they must be installed before refacing the seats if the equipment used has a valve guide pilot.

The valve seat width after refacing should measure not more than $\frac{5}{64}$ in. The width may be checked by placing a scale across the face of the seat.

A simple check can be made to prove the fit of the valve in the valve seat by spreading a thin film of Prussian Blue on the valve face and then inserting the valve into the valve seat. With hand pressure, rotate the valve ¼ turn and then remove it and observe the transfer of Prussian Blue to the valve seat. An uneven transfer of Prussian Blue will indicate an inaccurate valve and valve seat refacing operation.

VALVE SEAT INSERTS

All Engines

Whenever a valve grind job is being done, check the exhaust valve seat inserts. If one is found to be cracked or loose, it should be removed with a puller and the recess on the block or head carefully cleaned before installing the new seat.

To insure the proper press fit, shrink the insert by packing it in dry ice for about an hour before driving it in place.

Oversize inserts are available when required and the recess should be counterbored carefully to accomodate the oversize insert used.

VALVE SPRINGS

All Engines

After taking out the valves, remove the springs and wash them with gasoline or other suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a suitable test fixture if one is available. If a fixture is not available at least check the free length of each spring by standing it alongside a new spring.

Any spring that does not conform to

Fig. 3 Cylinder head and manifold tightening. Le Roi engine

Fig. 5 For correct valve timing, gear marks should be matched as shown. Autocar engines

Fig. 6 Timing gear cover details. Le Roi engines

the pressure specifications (see *Tune Up & Valve Specifications* table) within 10% should be replaced. Likewise, any spring that stands shorter than the new spring used for comparison should be discarded. Of course, cocked springs should be scrapped.

VALVE GUIDES, REPLACE

All Engines

Clean the valve guides with a wire guide brush and clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads as well as the gum which might have accumulated on the stems.

Check the clearance between valve stems and guides carefully. Excessive clearance between valve stems and guides will cause improper seating and burned valves. When there is too much clearance between intake valve stems and guides, there is a tendency to draw oil vapor through the guide on the suction stroke, causing excessive oil consumption, fouled spark plugs and poor low speed performance.

Valve stem-to-guide clearance may be checked with special "GO" and "NO-GO" gauges. Lacking these, an alternate method is to take a new valve and place it in each valve guide and feel the clearance by moving the valve stem back and forth. If this check shows excessive clearance, it will be necessary to replace the guides that are worn as indicated by this test. If the clearance is not excessive when checking with a new valve but is excessive when checked with the old valve, it is an indication that the old valve stem is worn and a new valve must be installed.

VALVE LIFTERS

Autocar Engines

Valve lifters are of the hollow mushroom type operating in individual cast iron guides clamped to the cylinder block. This construction permits their removal without disturbing the camshaft or valve mechanism.

Le Roi Engines

Barrel type lifters operate in bores for each bank of cylinders directly over the camshaft to transmit the cam lift to the valve train. The lifters can be replaced without removing the camshaft.

TIMING GEARS

Autocar Engines

The proper timing of the valves depends on the proper meshing of the camshaft gear with the crankshaft and idler gears. These gears are clearly marked as shown in Fig. 5. The tooth on the crankshaft gear with the single punch mark must mesh between the two marked teeth on the idler gear. Also the single tooth on the idler gear that is punch marked must mesh between the two marked teeth on the camshaft gear.

Le Roi Engines

The gear cover houses the crankshaft and camshaft gears, tachometer drive, accessory drive shaft, and the accessory drive housing mounted on the gear cover, Fig. 6.

To maintain perfect gear alignment, the accessory drive shaft for the water pump, governor and distributor is rigidly supported in three bearings, and is pressure lubricated from the engine's lubrication system. Rotation of this shaft is effected by a gear drive from the camshaft. An oil seal on the water pump end of the shaft prevents leakage of oil from the bushing located in the gear cover. To remove the gear cover:

1. Remove water pump cover, impeller, seal and seal seat.
2. Remove water pump body.
3. Remove manifolds, distributor, governor and rocker arm cover.
4. Disconnect oil line from accessory drive housing.
5. Unfasten oil pan from gear cover and take off cover. Reverse the order of the above procedure to reassemble, being sure to install new oil seals at the crankshaft and accessory drive shaft.

The accessory drive shaft oil seal may be removed without taking off the gear cover by cutting it with a sharp chisel and hooking it straight out. When replacing this seal use a sleeve to drive it in the gear cover hole as far as it will go, being careful not to damage the seal.

Timing the crankshaft and camshaft after one or the other gear has been removed requires that the timing marks on both gears be aligned as shown in Fig. 7.

Backlash originally provided for these gears is .006".

Fig. 7 Valve timing marks. Le Roi engine

CAMSHAFT & BEARINGS

Autocar Engines

To assure proper camshaft fit, camshaft bearings should be reamed *after* the cylinder block is bolted to the crankcase. Be sure the oil holes in the bearings are in line with the corresponding holes in the crankcase to assure adequate lubrication.

Camshaft end play is controlled by a fibre washer at the front end of the shaft. At long intervals, or when the engine has been disassembled for repairs, the end play should be checked and if in excess of about .006", install a new washer.

Le Roi Engines

These engines are equipped with shell type bearings which require reaming after installation. When new bearings are installed, be sure the oil holes in the bearings are aligned with the oil feed holes in the block to assure adequate lubrication.

Fig. 8 Installing cylinder sleeve in Le Roi engine. Packing rings must be well soaped to prevent their pulling out the grooves

PISTONS & RODS, REMOVE

All Engines

After removing the cylinder head and oil pan, examine the cylinder bores above the ring travel area. If the bores are worn so that a shoulder or ridge exists at this point, remove the ridge with a ridge reamer to avoid damaging rings or cracking ring lands of pistons during removal.

Remove the connecting rod caps and push the pistons and rods out of the cylinders, using care to prevent rod bolts from nicking crankshaft journals.

Make sure the rods and pistons are properly numbered so they can be reinstalled in the original locations. It is advisable to install caps on rods to avoid mixing parts.

PISTON & ROD, ASSEMBLE

Autocar Engines

Assemble the piston to the connecting rod so that when the assembly is installed in the block the T-slot side of the piston faces away from the camshaft side of the engine.

Le Roi Engines

Assemble the pistons to the connecting rods so that when the assembly is installed in the block the T-slot side of all pistons face the camshaft.

CYLINDER SLEEVES, REPLACE

Le Roi Engines

Iron alloy cylinder sleeves or liners are used to afford a replaceable wearing surface and form the inner water jacket surface. Neoprene rings in the liner grooves seal the water jackets at the bottom of the liner, while at the top end the cylinder head gasket provides the seal.

Wear in the liner to a point where piston-to-cylinder liner clearances become excessive may be suspected when blow-by, low compression pressures, smoky exhaust and high oil consumption indicate leakage around the piston.

Soak the carbon and oil deposits with solvent or gasoline and thoroughly clean the liner bore. Slight scratches and the ring travel ridge may be removed by scraping. The use of emery cloth is not recommended.

To determine the cylinder liner wear, traverse the bore with a dial indicating micrometer and note the average reading.

The liner may be removed by driving it up from the bottom with a mallet and a hard wood block, or with a liner puller. To seal the crankcase properly, the bore and upper seating surfaces must be absolutely clean.

Before inserting a liner, install the two packing rings and soap them liberally to prevent their pulling out of the grooves, Fig. 8. Guide the liner into the bore and drive it in place carefully so as to avoid damaging the sealing rings.

Always test the cooling system for leaks into the crankcase after replacing a cylinder liner.

PISTONS, REPLACE

All Engines

When fitting a piston in the cylinder block, wipe the cylinder bore clean with a cloth and insert the piston upside down with a feeler gauge of the proper width and thickness (given below) between the cylinder wall and thrust side of the piston. With the piston at room temperature, it should require the lbs. pull (given below) to remove the feeler with the piston held stationary. The lb. tension is measured with a spring scale attached to the feeler.

The fit of the piston should be checked at different points in the cylinder bore. And after fitting, each piston should be stamped with a number or otherwise marked with the cylinder number to which it belongs.

Engine	Feeler Gauge Thickness	Width	Lb. Pull
Autocar	.003″	½″	4-5
Le Roi	.002″	½″	10

Whenever a single piston is replaced in service, the new piston should match the weight of the old piston within ¼ oz. in order to retain balance in the engine.

PISTON RINGS, REPLACE

All Engines

When new piston rings are to be installed without reboring cylinders, the glazed cylinder walls should be slightly dulled, but without increasing the bore diameter. This is done with a "Glazebuster" or with a hone equipped with the finest grade of stones.

New piston rings must be checked for clearance in piston grooves and for gap in cylinder bores. Cylinder bores and piston grooves must be clean, dry and free of carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and a false measurement of clearance will result.

If the piston grooves have worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of the new rings and the ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

To check the end gap of rings, place the ring in the cylinder in which it will be used. Square it in the bore by tapping with either end of the piston, then measure the gap with feeler gauges. If necessary to increase the gap, file the ends of rings carefully with a smooth file.

PISTON PINS, REPLACE

All Engines

Piston pins are of the full floating type, being free to rotate in the piston bosses as well as in the connecting rod bushings at operating temperatures. Snap rings, located in the grooves in the piston bosses, prevent the pins from contacting the cylinder walls.

To fit a pin, heat the piston in a pail of boiling water until heated thoroughly. Then remove the piston and quickly insert the pin. A good fit is one which requires a slight push of the thumb to insert the pin.

ROD BEARINGS, REPLACE

All Engines

Connecting rods are fitted with precision type bearings, held in position by locking lugs which fit into grooves cut in the rods and in the caps.

Bearing clearance may be checked with Plastigage, which is available at any auto parts jobber. Instructions for its use are furnished with the package.

Lacking Plastigage, use a piece of tough paper or shim stock ¾″ square which measures about .0005″ under the maximum allowable bearing clearance. Oil the shim on both sides and lay it in the center of the bearing. Install the assembled bearing and cap and tighten the cap nuts to the torque given in the table.

The clearance is correct if the rod can be moved endwise when tapped lightly with a hammer. If the rod can be moved endwise by hand, clearance is too great. On the other hand, if the rod will not move when tapped lightly with a hammer, not enough clearance is present.

MAIN BEARINGS, REPLACE

Autocar Engines

On 377 engines before Eng. No. 25-6878, the main bearings are provided with a single laminated shim in each bearing for adjustment. After this Eng. No., no shims are used.

Fig. 9 Inserting crankshaft oil seal. Le Roi engine

On 447 and 501 engines the bearing shells are located by means of dowel pins in the bearing caps. No shims are provided for adjustment. On 377 engines, the bearings are held in place by locking lugs which fit into grooves milled in the crankcase and in the bearing caps.

Main bearings can be replaced without removing the crankshaft.

Le Roi Engines

Insert type bearings are used in all these engines and can be replaced without removing the crankshaft.

Fitting Main Bearings

On all engines, main bearings should be replaced in sets and under no circumstances should they be filed or otherwise altered in an attempt to affect an adjustment.

Plastigage may be used to check the fit of bearings and instructions for its use are furnished with the package.

CRANKSHAFT END PLAY, ADJUST

All Engines

Crankshaft end play is controlled by thrust washers on each side of the center main bearing on Autocar engines, by flanges on the front main bearing on Continental engines, and by flanges on the center main bearing on Le Roi engines.

Through normal wear, end play will seldom become excessive but whenever new bearings are fitted, check the end play which should be between .003″ and .007″.

Wear of the thrust bearing, usually caused by undue thrust loads, may be detected by knocks in the vicinity of the thrust bearing. To check this condition, remove the oil pan and insert feeler gauges between the bearing flange (or thrust washer) and crankshaft. If the end play is excessive, install a new thrust bearing or on Autocar engines, new thrust washers.

CRANKSHAFT OIL SEAL, REPLACE

Autocar Engines

Oil sealing at the rear main bearing is controlled by an oil slinger, integral with the crankshaft, running in a groove leading into the oil pan.

Le Roi Engines

Sealing around the crankshaft at both ends is provided by split felt rings held in place in recesses in both the crankcase and oil pan. Return oil grooves are cut into the crankshaft.

Insert the oil seal into the grooves provided in the crankcase, Fig. 9, making certain no part of the oil seal projects above or below the groove edge. Do not trim the edges of the oil seals.

Coat the seals with graphite and oil after they have been installed. Then tighten the oil pan to crankcase so that the ends of each felt half meet to form the proper seal.

OIL PUMP REPAIRS

Autocar Engines

The oil pump on these engines are of the positive gear type which can be removed after dropping the oil pan.

These pumps can easily be disassembled by taking off the upper drive gear and bottom cover, after which the component parts can readily be removed.

Le Roi Engines

The gear type oil pump, Fig. 10, is mounted on the front main bearing cap and is driven by the crankshaft gear. A pressure relief valve, built into the pump, continually by-passes the excess oil pumped over that required to lubricate the engine to the pump suction side and maintains correct oil pressure.

The oil pressure relief valve depends upon free movement of the plunger to operate correctly. If erratic oil pressure is traced to the relief valve, remove the oil discharge tube and tube connection. Pull out the spring and plunger and clean out the bore. Do not stretch or shim the spring to correct valve operation.

During any general engine overhaul, the oil pump should be disassembled, cleaned and inspected. Severe sludging may require an occasional disassembly to keep the pump passages clean.

Low oil pressure traced to the oil pump may be due to worn gears or restricted pump passages or excessive clearances.

WATER PUMP REPAIRS

Autocar 377 Engine

Disassemble—Remove the pump from the engine and take off the cover, Fig. 11. Using a puller, remove impeller with seal from shaft. Remove snap ring and withdraw seal from impeller hub. Remove lock ring and press shaft and bearing from body.

Inspection—If the sealing face of the pump body is pitted or grooved, this surface should be refaced or a new body installed. If the impeller is corroded it should be replaced, using a new impeller

Fig. 10 Oil pump service details. Le Roi engine

Fig. 11 Water pump. Autocar 377 engine

Fig. 12 Water pump. Autocar 447 and 501 engines

Fig. 14 Water pump service details. Le Roi engine

and seal assembly. A new seal should always be installed whenever the pump is disassembled. If the pump shaft bearings are noisy, a new shaft and bearing assembly should be installed.

Assemble—Press the bearing and shaft into the pump housing and lock in place with the lock ring. Apply a thin coat of light oil to the pump shaft and press the impeller and seal on the shaft until the face of the impeller is just flush with the end of the shaft.

Complete the assembly and install on the engine, making sure the pump coupling bushing is in place.

Autocar 447 & 501 Engines

Disassemble—Referring to Fig. 12, take off the cover and remove the impeller and seal from the pump shaft, using conventional puller in holes provided. Remove and discard seal from impeller hub. Remove lock ring from body and press out shaft and bearings. Remove lock rings and press bearings from shaft.

Inspection—If either bearing is noisy, replace with new part. Inspect face of body against which sealing washer turns. Surface should be smooth and free from scores. Reface if necessary. Discard impeller if found to be corroded.

Fig. 13 Location of water pump seal and seal parts. Le Roi engine

Assemble—Press front bearing against shoulder on pump shaft and secure with lock ring. Press rear bearing against shoulder on shaft and secure with lock ring. Press slinger on shaft against lock ring. Assemble shaft with bearings in body and secure with lock ring. Install new seal in impeller hub and lock seal with lock ring. Guide impeller and seal over end of shaft and press impeller on shaft until flush with end of shaft. Replace pump cover with new gasket.

Remove plug and fill housing with wheel bearing grease until it starts to come out of the small vent hole. Replace plug.

Assemble pump to engine, making sure dowel pins are in place. Replace drive coupling and elbows.

Le Roi Engines

The water pump circulates water from a common suction connection into each bank of the engine through individual discharge connections.

The pump is lubricated under pressure from the main lubricating oil system of the engine. The pump impeller is mounted on the front end of the accessory drive shaft.

Leakage of water from between the water pump and gear cover may be due to a defective sealing washer, Fig. 13.

To remove the water pump seal, loosen and remove the fan belts and water pump cover. Insert cap screws in the impeller, Fig. 14, and pull it off the pump shaft. It may be necessary to remove rust and scale from the holes. Slide the combination bellows and carbon seal washer off of the shaft. In all cases it is advisable to replace this seal and the seal seat, if necessary, whenever disassembling the pump because of its low cost and the likelihood of its being damaged during removal.

While the cover and impeller are removed, check the gear cover and accessory drive housing bushing clearance by jiggling the shaft. Any noticeable play in the shaft indicates the need for replacing the bushings.

If rust and scale deposits have accumulated in the pump body, remove them and flush entire cooling system.

IGNITION TIMING

If a timing light is to be used to set ignition timing, disconnect the vacuum advance pipe to the carburetor and place a piece of tape over open end of pipe. *This is important as carburetor trouble can affect timing adjustments.*

Lacking a power timing light, an accurate method of setting ignition timing with the engine stopped is with the aid of a jumper light. Be sure to use a light bulb that corresponds with the system voltage of the vehicle.

1. Remove distributor cap and rotor and see that the breaker gap is set according to specifications.
2. Rotate engine until No. 1 cylinder is at the ignition timing point as indicated by the timing pointer and timing mark being lined up with each other.
3. Connect the jumper light between distributor ignition terminal and ground.
4. Turn on ignition switch.
5. Loosen distributor and turn it in the direction of normal rotation until the points just close (light out). Then slowly turn distributor in the opposite direction just to the exact point that the light goes on. Tighten distributor in this position.

Fig. 15 Ignition wiring diagram. Le Roi engine

Fig. 16 Zenith carburetor float settings

CARBURETOR, ADJUST

Float Setting, Zenith Carburetors

Float setting should be checked by holding the cover assembly upside down. With the weight of the float holding the needle valve seated, the distance from the far side of the float to the housing should be as given below. See Fig. 16 for type of float used.

Carb. Model	Setting
63AW12	$1\frac{19}{32}''$
63AW14	$2\frac{1}{64}''$

Float Setting, Holley Carburetors

When checking the fuel level in an open vessel, under 4 lbs. pressure on the 885-JJSG carburetor the fuel level should be $\frac{19}{32}''$. Under $4\frac{1}{2}$ lbs. pressure on the 885-FFG carburetor the fuel level should be $\frac{1}{2}''$. Measurement is taken from the float chamber cover with gasket in place to the level of the fuel in the bowl.

The float level can be set accurately by gauging the distance between the bottom of the floats and the chamber cover surface. When setting the float level, it is important that both the "Open" and "Closed" position of the floats be checked, Fig. 17.

To gauge the "Closed" position of the floats, hold the float chamber cover upside down. Then measure the distance from the float chamber gasket to what would normally be the bottom side of the free end of the floats. The distance should be $1\frac{5}{16}''$ on the 885-JJSG unit and $\frac{5}{32}''$ on the 885-FFG carburetor. Measurement is taken with the fuel [illegible] the 885-FFG carburetor is when the valve in the closed position and the float chamber cover gasket in place. To correct the float setting for this position, the float lever arms should be bent up or down to bring the floats within the established limits and thus correct the fuel level for best operation. Pushing the floats up or toward the float cover, raises the fuel level, and down or away from the cover lowers the level.

The "Open" position is gauged by raising the floats up until the float stop arm comes to rest against the inlet needle housing. Then measure the float setting in the same manner as for the "Closed" position. The distance should measure $1\frac{15}{16}''$ on the 885-JJSG unit with the gasket in place and the float in the position illustrated in Fig. 20. Corrections for this setting can be made by bending the stop arm on the float lever.

The "Open" position of the float on the 885-FFG carburetor is when the float rests on the bottom of the bowl.

Fig. 17 Float setting. Holley 885-JJSG carburetor

Idle Mixture Setting

The idle needle valve setting from the closed position is from $\frac{3}{4}$ to $1\frac{1}{4}$ turns open on Holley carburetors and 1 turn on Zenith carburetors. Care should be taken not to jam the needles against the seat tight enough to groove the points. If this occurs, the needles will have to be replaced before a satisfactory adjustment can be made.

When the engine has been warmed up, turn one idle needle in until the engine starts to slow down, then turn it out until it again slows down. A point midway between these two will be very close to the correct idle mixture. Repeat this procedure for the other needle (if used). When this is done, cross check by repeating both of the above procedures. The idle speed should be reset, if necessary, between the above operations.

Clutch Section

LIPE-ROLLWAY TYPE ML

Single Plate Type

This clutch, Fig. 1, is a single plate, dry disc type, in which pressure on the driven disc is provided by a heavy spiral spring acting through 20 interlocked levers. It is used by Autocar in 13", 14" and 15" sizes.

When the clutch pedal is depressed, the release sleeve moves toward the flywheel and acting through the fulcrum ring and the clutch pressure levers, relieves the pressure on the clutch pressure plate. The four retractor springs pull the pressure plate away from the flywheel so that there is no longer any contact between the pressure plate and the clutch disc facing. This action disengages the clutch, permitting the flywheel to revolve while the clutch shaft remains stationary.

When the clutch pedal is released, the pressure of the spring is transmitted through the ball-mounted pressure levers to the clutch pressure plate, moving it toward the flywheel and compressing the clutch disc facing, thus engaging the clutch. Since the pressure plate moves in a parallel plane to the flywheel face, every square inch of friction surface of the disc comes in contact with the flywheel at exactly the same instant, insuring smooth engagement.

Adjustment

The original setting of the clutch pro-

Fig. 1 Lipe-Rollway Type ML multiple lever clutch

Fig. 2 Adjusting points on Lipe-Rollway Type ML clutches

vides for 1½" free movement of the clutch pedal. As the facings wear, the clutch sleeve moves toward the clutch release bearing, reducing the clearance and automatically cutting down on the free travel of the clutch pedal. When this free travel drops to about ½", the clutch should be readjusted.

Never wait for a clutch to slip before adjusting it. If the facings once become burned, they disintegrate rapidly, and a new clutch disc assembly may be required.

When reduced pedal free travel indicates wear in the clutch, the distance between the clutch sleeve and the rear face of the flywheel ring, as indicated by dimension "A" in Fig. 2 should be checked. When the clutch is properly adjusted, this measurement should be as follows:

Autocar Part No.	Dimension "A"
3DA030	1 to $1\frac{1}{16}$"
3DA030A	$1\frac{1}{16}$ to 1⅛"
3NA030	$1\frac{1}{16}$ to 1⅛"
3NY030	1⅛ to $1\frac{3}{16}$"
3NY030A	$1\frac{5}{16}$ to 1⅜"
All 15" clutches	$1\frac{3}{16}$ to 1¼"

Do not adjust the pedal or linkage to correct free pedal movement. To make the adjustment, proceed as follows:

1. Block pedal in depressed position.
2. Back off the four flywheel ring stud nuts five full turns each.
3. Remove block from clutch pedal and engage clutch.
4. Remove one shim from under each adjusting strap, Fig. 3, using a pair of sharp nose pliers. *Make sure the same number of shims is removed from under each strap, and that no broken portion of a shim is left under the clamp.*
5. Block the pedal in the depressed position again and tighten the four flywheel ring stud nuts. Remove pedal block.
6. Using the gauge, Fig. 2, or a straight edge, check dimension "A".
7. After proper adjustment has been made, check the distance "B", Figs. 2 and 4, from the release bearing to the clutch sleeve. If this dimension is less than ⅛" or more than $\frac{5}{32}$", it will be necessary to adjust the pedal linkage to correct it.

Driven Disc, Replace

1. After removing the transmission, unfasten and remove the clutch from the flywheel.
2. Remove the four flywheel ring stud nuts and the adjusting straps one at a time, and place a total of 6 shims under each strap (7 per stud on clutch No. 3NA030).
3. Examine flywheel, making sure friction face is clean, smooth and dry.
4. Check release bearing and pilot bearing to make sure they are in good condition. Both these bearings are factory sealed and require no further lubrication.
5. Install a new driven disc assembly and bolt the clutch to the flywheel, using a spare splined shaft to align the disc. Screw in each bolt until it just contacts the cover plate, then gradually tighten alternate bolts until the clutch is drawn up evenly against the flywheel. Tighten the remaining bolts that secure the clutch to the flywheel.
6. After the clutch is installed, check for proper release. Adjust clutch and pedal linkage as outlined previously.

Pressure Plate, Replace

A pressure plate "dished" in excess of .015" or badly scored should be replaced with a new part. After removing the transmission and the clutch from the flywheel, proceed as follows:

1. Place clutch on an arbor press with pressure plate down and compress the spring as far as possible.
2. Remove four retractor springs after first removing the pins.

3. Slowly release the press, allowing clutch spring to return to normal position.
4. Holding clutch assembly together by hand, turn it over and carefully lift off the pressure plate.
5. Install new pressure plate, turn clutch over and compress in arbor press.
6. See that retractor springs are in place and install pins.
7. Remove clutch from press and install on flywheel.

Two Plate Clutch

This clutch is a two plate, dry disc type with the two driven plates mounted on the splined clutch shaft. The driven disc, which separates these two plates, Fig. 5, is mounted within the flywheel on four drive pins. The clutch operates in substantially the same manner as the single plate type.

Clutch Adjustment

This clutch is adjusted in the same manner as the single plate type. Dimension "A" should be 1⅛" to $1\frac{3}{16}$" on Autocar Clutch No. 3E030A, and 1¼" to $1\frac{5}{16}$" on Clutch No. 3E030B. All other items of adjustment are the same as single plate units.

Driven Discs, Replace

1. After removing the transmission, unfasten the clutch from the flywheel and remove clutch cover plate, driving disc and driven discs.
2. Examine flywheel, making sure friction face is smooth, clean and dry. Check pilot and release bearings to make sure they are in good condition. Both these bearings are factory sealed and require no further lubrication.
3. Inspect driving disc drive pins in the flywheel. Make certain that shanks of pins are press fitted into flywheel rim, and that heads are squarely aligned with the friction face of flywheel. If drive pins are found to be loose, a .015" oversize pin should be installed. This will require reaming the holes in the flywheel rim to .5145"-.5155". When heads of drive pins are squarely aligned, lock in position with set screw. If set screws are not provided, check to see that the four capscrew holes adjacent to the drive pin holes are tapped all the way through. If not deep tapped, drill with $\frac{5}{16}$" tap drill and a ⅜"-16 tap and insert ⅜"-16x⅜" Allen head set screw.
4. Place driving disc over drive pins and check clearance between heads and slots in driving disc. A side lash of .007" to .011" is required.
5. Using a spare splined clutch shaft, install the driven discs and driving disc as follows:
6. Install driven disc marked "flywheel side" next to flywheel with marked side next to flywheel face.
7. Install driving disc, making certain its rotation is in the direction of the arrows appearing on one side near the bore.
8. Install the driven disc marked "pressure plate side" with the marked side next to the pressure plate.
9. Bolt the cover plate to the flywheel, gradually tightening opposite bolts until assembly is drawn tight to flywheel.
10. Adjust clutch and pedal linkage.
11. Remove dummy clutch shaft and install transmission.

Fig. 3 Removing shims to establish dimension "A". Lipe-Rollway Type ML clutches

Fig. 5 Layout of Lipe-Rollway Type ML two plate clutch parts

Pressure Plate, Replace

A pressure plate "dished" in excess of .015", badly scored or having a fulcrum edge in excess of $\frac{1}{16}$" in width, Fig. 6, should be replaced with new part. After removing transmission and cover plate from flywheel, proceed as follows:

1. Place cover plate in arbor press with pressure plate down and compress spring as far as possible.
2. After removing pins and washers remove springs from studs.
3. Slowly release arbor press, allowing clutch spring to return to normal position.
4. Holding cover plate together by hand, turn it over carefully and lift off pressure plate.
5. Install new pressure plate, turn cover plate over and compress in arbor press.
6. With retractor springs over studs, install washers and pins. Retainer washers should have the cupped side up so as to lock the pins in position.
7. Remove cover plate from press and install on flywheel.

LONG 15-4A

This type clutch, Fig. 7, is a dry disc type in which pressure is exerted against the pressure plate by a series of coil springs. This pressure is augmented by six specially weighted clutch release levers.

Each of these levers, made of forged steel and mounted on needle roller bearings, is weighted at the outer end in such a way that the faster the clutch revolves the more pressure is exerted against the clutch plate. Thus the centrifugal force action supplements the normal spring pressure against the clutch plate, thereby increasing the torque transmitting ability of the clutch.

Fig. 4 Checking clearance between release bearing and release sleeve. Lipe-Rollway Type ML clutches

Fig. 6 Check fulcrum edge of pressure plate and adjusting plate. If in excess of 1/16", replace part. Lipe-Rollway Type ML clutches

With this clutch, no internal adjustments are necessary to compensate for wear.

Clutch Service

Unless special clutch rebuilding equipment is available, it is recommended that the clutch assembly be exchanged for a rebuilt unit should the clutch require rebuilding. The driven disc, however, may be replaced as follows:

1. Remove transmission and bell housing.
2. Using six 3/8-16 x 1¼" capscrews, screw them into the cover plate in the holes provided until the screw heads just bottom to hold the springs compressed.
3. Unfasten the cover plate from the flywheel.
4. Remove the driven disc.
5. Place the new disc on the flywheel with the short hub toward the flywheel.
6. Install the clutch assembly.
7. Push an aligning shaft (a spare transmission shaft will do) through the clutch hub and pilot bearing.
8. Tighten the cover-to-flywheel screws down evenly and securely, giving each a few turns at a time until all are seated.
9. Remove the aligning shaft and the six screws used to keep the springs compressed when clutch was removed.
10. Before attaching the transmission to the engine, check the release levers and bearing for clearance. Use care to see that the flexible oil tube does not rub against the cover plate.

Fig. 8 Clutch pedal adjustment. Trucks with long clutch

Fig. 7 Long 15-4A model single plate clutch

Clutch Pedal, Adjust

Clearance between the clutch release bearing and clutch levers is made by loosening the lock nut and turning the set screw, Fig. 8, as required to provide 1¼" to 1½" free pedal travel.

Adjustment of the release levers in the clutch assembly should never be attempted unless the assembly is removed and placed on a clutch rebuilder.

SPICER TWO PLATE CLUTCH

This type clutch, Fig. 9, is a two plate, dry disc type with the two driven plates mounted on the splined clutch shaft. The driving disc, which separates these two plates, is mounted within the flywheel on four pins. As an aid to gear shifting, a clutch brake is provided which comes into action when the clutch pedal is fully depressed.

Adjustment

1. Remove clutch housing cover and check clearance between clutch trunnion and forward side of clutch plate, Fig. 9. If the dimension is not 3/8" to ½", adjust as follows:
2. Remove capscrew and lock on flywheel ring. Block clutch pedal in depressed position and, with a hammer and drift, turn clutch ring clockwise to decrease distance between clutch trunnion and brake. Turn ring counterclockwise, if necessary, to increase clearance.
3. Engage clutch and recheck clearance.
4. Adjust clutch pedal linkage so that pedal free travel is 1¼" to 1½".
5. Run the engine and check to see that the full release of the clutch is obtained before the clutch brake comes into action. Gears should shift freely with no noticeable drag of clutch plates.
6. If clutch does not release before clutch brake comes into action, it will be necessary to readjust the clutch as outlined above.
7. As a final check, when the clutch pedal is fully depressed, it should have a minimum clearance of ½" above the toeboard. Readjust pedal linkage if necessary.

Fig. 9 Spicer two plate clutch

Driven Discs, Replace

1. After removing the transmission, insert two ¾" blocks between clutch release bearing and clutch cover plate.
2. Remove capscrew and lock and release adjusting ring by turning it counterclockwise.
3. Remove screws attaching spring plate and hub assembly to flywheel.
4. Remove cover plate, pressure plate, driving disc and driven discs.
5. Check clutch pilot bearing and replace if worn. Pack with bearing grease.
6. Using spare splined clutch shaft, assemble clutch driving plate, driven discs and clutch cover plate. *Driven discs must be positioned with offset*

hubs as shown in Fig. 9.
7. Bolt clutch to flywheel with dummy shaft in position and two ¾" wooden blocks between release bearing and cover plate.
8. Remove blocks and dummy shaft and install transmission. Then adjust the clutch and pedal linkage as outlined previously.

Transmission & Rear Axle Section

For Fuller and Spicer transmissions used on Autocar trucks, see the "name" chapter for service procedures and lubricant capacities.

For Timken (Rockwell-Standard) driving axles used on Autocar trucks, see Timken chapter.

① Model number embossed on carrier housing or axle housing.

AUTOCAR ET, FF, FT, GG, GH, TK

Double Reduction Axles

These double reduction axles are of full floating design in which all gears are mounted in a gear carrier which is detachable as a unit from the axle housing. Double reduction is accomplished by a spiral bevel pinion and gear in conjunction with a spur gear second reduction. The bevel pinion shaft, jackshaft and differential are mounted on tapered roller bearings that are fully adjustable for wear. Figs. 1 and 2 illustrate two designs.

Gear Carrier, Remove

1. Drain lubricant from housing.
2. Disconnect propeller shaft at companion flange.
3. Remove axle shafts. On ET and FT models, remove twelve nuts which secure axle shaft to wheel hub. Strike center of axle shaft flange a sharp blow with a hammer to loosen shaft.
4. Remove the carrier from the axle housing. On ET and FT models, remove the carrier stud nuts and, using two puller screws, withdraw the carrier from the housing. On TK, GG and GH models, remove the inspection cover from the top of the carrier and cut out the lock wire holding the carrier stud nut; then after removing all the housing stud nuts, remove the carrier from the housing.

Gear Carrier, Install

1. On ET and FT models, using a new gasket, install the gear carrier in the housing. Apply two upper nuts before the carrier is drawn up tight. On FF, GG, GH and TK models, install the gear carrier in the housing, using a new gasket, entering bearing cap dowels in their sockets, Fig. 2. Install the carrier dowel pins and tighten all carrier stud nuts.
2. On TK, GG and GH models, install locking wire in the carrier stud nut under the carrier inspection cover, and replace the inspection cover with a new gasket.
3. Install axle shafts, assemble propeller shaft to companion flange and fill housing with lubricant to the proper level.

Differential & Ring Gear, Disassemble

1. With center punch, mark carrier and caps to insure correct reassembly. Also mark two halves of differential case and ring gear.
2. Remove differential bearing adjusting ring lock from each carrier cap.
3. Remove carrier cap stud nuts or capscrews. Remove caps and lift ring gear and differential assembly out of gear carrier.
4. Pull bearing cones from differential case with bearing puller.
5. Remove nuts and drive bolts out of differential case. Separate two halves of differential case from ring gear.
6. Remove differential spider, pinions, side gears and thrust washers, Fig. 3.

Differential & Ring Gear, Assemble

1. Place recess side of differential case on bench and assemble side gear with thrust washer in it.
2. Install differential spider with pinions and thrust washers in differential case.
3. Install other side gear and thrust washer on top of pinion.
4. On ET, FT and FF models, one side of the inner face of the ring gear is

Fig. 3 Layout of differential and ring gear parts. Autocar all models

Fig. 4 Layout of jackshaft and bevel gear parts. Autocar ET, FF, FT, TK

Fig. 5 Layout of jackshaft and bevel gear parts. Autocar GG, GH

machined with a $\frac{1}{32}$" step, and this side must be uppermost when placing the gear on the assembled half of the case.

5. Place tongue side of differential case on top of the ring gear and drive it down tight with bolt holes registering and center punch marks matched.
6. Bolt complete assembly together, driving the bolts through from the tongue side of the case. Secure nuts with cotter pins.
7. Press bearing cones on differential.
8. With bearing cups over the cones, assemble differential and ring gear in carrier, centering gear with spur pinion.
9. Install adjusting rings and bearing caps, making sure threads in rings mesh with threads in carrier and caps. Tighten bearing cap nuts or cap screws and then slacken off sufficiently to allow rings to turn.
10. With adjusting rings, tighten up on differential bearings until there is a slight drag when the ring gear is turned by hand. After bearings are properly adjusted, if ring gear and pinion are not centralized, gear may be moved sideways by loosening one adjusting ring and tightening the opposite ring a corresponding amount.
11. Tighten bearing cap stud nuts or capscrews and lock with cotter pins or, where capscrews are used, apply locking wire.
12. Apply adjusting ring locks and bend up locking washers.

Jackshaft & Bevel Gear, Disassemble

1. Referring to Figs. 4 and 5, remove cap screws holding bevel gear oil trough.
2. With center punch, mark bearing cages and carrier to aid in reassembly.
3. Remove cap screws from each bearing cage and withdraw cages from carrier with the aid of jack screws.
4. Wire shim pack to each bearing cage.
5. Remove jackshaft through rear of gear carrier.
6. On ET, FT, FF, TK models, cut lock wire and remove two cap screws holding retainer plate.
7. Use bearing puller to remove bearing cones from jackshaft.
8. Press bevel gear off jackshaft in arbor press. On GG and GH models, first remove locking wires and cap screws before pressing off gear.

Jackshaft & Bevel Gear, Assemble

1. Press bevel gear on jackshaft in arbor press. Press gear against shoulder on jackshaft on all models except TK with 25-tooth bevel gear. With the 25-tooth bevel gear a spacer is required between gear and shaft shoulder (part 4TG21219).
2. On GG and GH models, secure with cap screws and locking wire.
3. Press bearing cones on jackshaft.
4. On ET, FF, TK models, install bearing retainer plate on end of jackshaft and secure with cap screws and locking wire.
5. Assemble jackshaft in gear carrier with bevel gear on right side.
6. Replace bearing cages with original shim pack under each cage.
7. New bearings should be adjusted so there is a slight drag when the shaft is turned by hand. Add or remove shims under bearing cages as required to obtain correct result.
8. Install oil trough to carrier housing.

Bevel Pinion & Cage, Disassemble

1. Referring to Fig. 6, remove cap screws and withdraw pinion cage from carrier with the aid of jack screws.
2. Wire shim pack to bearing cage.
3. On ET, FF, FT models, remove cotter pin and nut holding companion flange on keyed end of shaft. Pull off flange and remove drive key, pinion shaft bearing lock nuts and lock washer. On GG, GH and TK models, pull companion flange off splined end of pinion shaft.
4. Place bearing cage in arbor press with gear down and apply pressure to the flange end of pinion shaft. Press shaft from cage.
5. Remove shims, spacer and bearing cone from pinion shaft.
6. Remove pinion cage cap and gasket; also oil seal from bearing cap.

Bevel Pinion & Cage, Assemble

The use of a dummy pinion shaft having the bearing lands turned down .002 to .005" undersize will greatly facilitate the proper adjustment of the pinion shaft bearings. After securing the correct adjustment, the bearing cones, spacer and shims can be transferred to the standard pinion shaft for assembly in the bearing cage.

1. Install rear bearing cone on dummy pinion shaft tight against gear.
2. Assemble bearing spacer on shaft, together with shim pack as removed.
3. On ET, FF and FT models, insert pinion shaft in bearing cage and tap front bearing cone into place, tightening the assembly with the bearing lock nut.
4. On GG, GH and TK models, insert pinion shaft in bearing cage and tap front bearing cone into place. Place a sleeve of suitable length over end of shaft so that approximately half of threads are exposed. Then tighten up on assembly with flange nut.
5. On all models, new bearings should be adjusted so there is a slight drag when rotating the pinion by hand. Correct adjustment is secured by adding or removing shims between the front bearing cone and bearing spacer.
6. Transfer bearing cones, spacer and shims from the dummy shaft to the standard pinion shaft for final assembly. On ET, FF and FT models, tighten the bearing nut, lock washer and jam nut and bend the lugs of the washer over the jam nut.

Fig. 6 Layout of bevel pinion and cage parts. Autocar GG, GH, TK

7. Install a new oil seal in the bearing cap and assemble the cap to the bearing cage, using a new gasket.
8. On ET, FF and FT models, install the companion flange drive key, flange, lock nut and cotter pin. On GG, GH and TK models, press the companion flange on the splined end of the pinion shaft and install the flange nut and cotter pin.
9. Assemble bevel pinion and cage in gear carrier, using shims removed on disassembly.

Bevel Gear & Pinion, Adjust

Correct adjustment of the spiral gear and pinion is essential to their proper operation. Unless there is nearly full tooth contact, excessive loads will be concentrated on small areas of the teeth and rapid wear will result.

In the trial set-ups, the pinion cage and jackshaft bearing cages may be pulled up with only four bolts each, two on a side, in order to facilitate the addition or removal of shims if required.

If a rear axle gauge (Tool G-1928) is available, it should be used in making the preliminary setting of the bevel pinion. This gauge is placed in the carrier housing in the position normally occupied by the jackshaft.

It will be noted that a number, such as +7 or −5, is etched on the rear face of the pinion. The dial on the gauge should be turned to bring the indicator pin in contact with the face of the gear at the point where this number appears.

The reading on the gauge should be within .003″ of the number etched on the face of the pinion. If the gauge reading exceeds this limit, it will be necessary to add or remove shims to alter the relation of the bevel pinion to the jackshaft.

Following the installation of the pinion assembly, the jackshaft should be placed in the carrier housing and the jackshaft bearings adjusted as outlined under "Jackshaft and Bevel Gear, Assemble".

Backlash—If rear axle gauge (G-1928) is not available, it will be necessary to check the backlash. Make preliminary check of backlash between the two gears with a dial indicator placed so that the stem bears against the heel of a bevel gear tooth. As the gear is rocked back and forth, without turning the pinion, the indicator should show .006 to .010″ backlash. Add or remove shims under the pinion bearing cage to adjust backlash.

Correct Tooth Contact—Paint the bevel gear teeth with a light coating of red lead, white lead or Prussian blue. Revolve the gears and observe the contact. A series of gear tooth contact illustrations appear in the *Eaton & Timken Rear Axles* chapter of this manual. Refer to these illustrations and correct as follows:

High Narrow Contact—To correct this condition, remove shim, allowing pinion to move toward gear. This adjustment may decrease backlash which can be readjusted if necessary by moving the bevel gear away from the pinion.

Sidewise movement of the jackshaft is accomplished by removing shims from one bearing cage and adding a corresponding number of shims under the opposite bearing cage. The bearing adjustment is not altered if this procedure is carefully followed.

Low Narrow Contact—With this condition, move pinion away from bevel gear by adding shims under the bearing cage. Correct the backlash by moving gear closer to pinion.

Heavy Heel Contact—To correct this condition, move the bevel gear closer to the pinion. Add shims under pinion bearing cage to maintain correct backlash.

Heavy Toe Contact—This condition is corrected by moving the bevel gear away from the pinion. To obtain proper backlash, remove shim from pinion bearing cage.

Steering Gear Section

ROSS GEAR

Twin Lever Mounted Type

The steering gear, Fig. 1, is the cam and twin lever type in which the cam is mounted on ball bearings and the lever shaft turns on steel-backed bronze bushings.

As the cam is turned by the wheel tube, the follower studs are pulled along the cam groove, causing the lever arm to rotate the lever shaft. The pitman arm, which is clamped on the splined end of the lever shaft and moves with it, turns the front wheels through the linkage.

Cam End Play, Adjust

1. Free the steering gear of all load by disconnecting the drag link from the pitman arm and loosening the steering column braces.
2. Loosen the lock nut and adjusting screw in the side cover to free the studs in the cam groove.
3. Remove the four upper cover stud nuts and raise the housing upper cover to permit removal of the adjusting shims, which are of .002″, .003″ and .010″ thickness.
4. Clip and remove one thin adjusting shim and then tighten down the cover with the four nuts and check the adjustment. There should be a slight drag but the steering wheel should turn freely with the thumb and forefinger lightly gripping the rim.
5. If necessary, remove or replace shims until the adjustment is correct.

Lever Shaft Backlash, Adjust

1. Centralize the steering gear by turning the wheel all the way to the right and from this point count the number of turns required to reach the end of travel to the left. Turn the wheel back exactly half this number of turns which is the mid-position.
2. Tighten the side cover adjusting screw until a very slight drag is felt through the mid-position when turning the steering wheel slowly from one side to the other. *The gear must not bind in any position. A slight drag should be felt in the mid-position only.*
3. After proper adjustment has been made, tighten the adjusting screw lock nut and recheck the gear for binding.

Stud Roller Bearing, Adjust

In most cases the adjustments outlined above will be adequate. However, in some cases it may be necessary to adjust the stud roller bearing units in the lever shaft.

The roller bearings should be preloaded at all times. A heavy drag should be felt when revolving the studs by hand. If a torque wrench is available, the bearings should be adjusted as follows:

Lever Shaft Dia.	Torque to Revolve Stud
1⅜"	3-4 in. lb.
1½"	3-4 in. lb.
1⅝"	4-8 in. lb.
1¾"	5-11 in. lb.

1. With lever shaft removed from steering gear housing, wash the bearings in solvent and blow dry with compressed air, using care not to spin the bearings. Lubricate bearings with light oil.
2. Straighten out prong of locking washer to release stud nut. Remove nut and install new locking washer.
3. While holding stud from turning with a suitable spanner wrench on the locking washer, tighten the nut as required to bring it within the proper torque limits.
4. When proper adjustment has been secured, bend prong of washer against side of nut to keep it from turning.
5. Lubricate bearings with gear oil and assemble lever shaft in gear housing.

Column Alignment

After the steering gear has been reassembled and all adjustments completed, tighten the mounting bracket as well as the column upper bracket and braces. If necessary, renew the bushing in the column top bracket. The steering column must not be sprung in any direction, and any misalignment must be corrected or it will produce stiffness in the steering gear.

Engine Section

Fig. 1 Cross section of L-head engine. Typical of 38B, 40B, 41BD, 42BD, 42BX, 42BY

ROCKER ARM SERVICE

Overhead Valve Engines

Sludge and gum formation in the rocker arms and shafts will restrict the normal flow of oil to the rocker arms and valves. Each time the rocker arm and shaft assemblies are removed they should be disassembled and thoroughly cleaned.

When disassembling rocker arms, place all parts on the work bench in their proper sequence to insure correct assembly.

Clean all sludge and gum formation from the inside and outside of the shaft. Clean oil holes and passages in the rocker arms and shafts. Clean the oil connector. Inspect the shafts for wear.

Check the ball ends of the rocker arms to be sure they are not pitted or rough. If used in this condition, it will be difficult to maintain valve clearances.

VALVES, ADJUST

All Engines

Adjust the valves to the clearances given in the *Tune Up & Valve Specifications* table. If the valves are to be adjusted warm, run the engine for about 30 minutes to normalize the expansion of all parts.

On overhead valve engines, be sure the cylinder head is properly tightened down before adjusting valve clearances.

CYLINDER HEAD, REPLACE

All Engines

When removing a cylinder head a chisel or screw driver should never be used to pry it loose from the cylinder block. Use an eyebolt in the third or fourth spark plug hole, lifting up on the eyebolt while tapping lightly around the edges of the head with a lead or rawhide hammer or mallet. Be sure all the head stud nuts or bolts have been removed before starting to remove the head.

In replacing the head, the stud nuts or bolts at the center of the head should be tightened first and then work outward from side to side and to the ends. Draw the nuts or bolts down evenly until all are normally tight. After the engine has run long enough to warm it up, make a final tightening with a torque wrench to the torque loads given in the *Tune Up & Valve Specifications* table.

On overhead valve engines, be sure to check the valve clearances after the final tightening.

Fig. 2 Side section of L-head engine. Typical of 38B, 40B, 41BD, 42BD, 42BX, 42BY

VALVES, REMOVE

L-Head Engines

After taking off the cylinder head, remove the valve chamber covers and use cloth to block off the holes in the valve chamber to prevent the valve locks from falling into the crankcase.

With a suitable valve spring compressor, raise the springs on those valves which are closed and remove the valve locks. Then turn the crankshaft until those valves which are open are closed and remove the remaining valve locks.

Remove all valves and place them in a board with numbered holes so that they can be identified as to the valve port from which they were removed.

Overhead Valve Engines

After removing the cylinder head and rocker arm assembly, use a suitable spring compressor to compress the springs. Remove the valve locks and springs. Check the keeper grooves in the valve stems for burrs and remove any burrs with a file to prevent scoring of valve guides. Remove the valves and place them in a board with numbered holes so they can be replaced in the same valve port from which they were removed.

VALVES, GRIND

All Engines

Clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads as well as the gum which might have accumulated on the stems.

In refacing valves, take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced. In other words, the valve head margin must be at least $\frac{3}{64}$", otherwise the valve must be replaced. This margin is the area above the contact surface of the valve face.

Inspect the valve seats in the block or head for cracks, burns, pitting, ridges or improper angle. During any general engine overhaul, it is advisable to reface the valve seats regardless of their condition. If new valve guides are required, they must be installed and reamed before refacing the seats if the equipment used for refacing the seats has a valve guide pilot.

The valve seat width after refacing should be a liberal $\frac{1}{16}$" for intake seats but not more than $\frac{3}{32}$" in any case. The width of exhaust seats should be $\frac{3}{64}$" to a liberal $\frac{1}{16}$".

A simple check can be made to prove the fit of the valve in the valve seats by spreading a thin film of Prussian Blue on the valve face and inserting the valve in the valve seat. With hand pressure, rotate the valve ¼ turn, remove it and observe the transfer of Prussian Blue to the valve seat. An uneven transfer will indicate an inaccurate valve and valve seat refacing operation.

Fig. 3 Details of "Roto Valve" mechanism used on 46B, 46BD, 48B and 48BD engines

VALVE ROTATORS

Overhead Valve Engines

Increased exhaust valve service in these engines is accomplished by the use of "Roto Valve" mechanism, Fig. 3, which is a special valve spring retainer and cap located on the end of the valve stem.

In operation, the rocker arm striking the cap lifts the retainer first, thus taking the spring load off the valve before lifting it from its seat. When the valve is in the raised position, it is free to rotate due to the vibration of the system.

When checking valve clearances, the feeler gauge is placed between the cap and socket as there is no other flat surface in the valve train.

VALVE SEAT INSERTS

All Engines

Since these inserts are too hard to reface by ordinary hand grinding methods, a high speed grinder or special lapping equipment should be used to perform this operation. When using this equipment, be sure valve guides are clean and the valve guide pilot is a snug fit in order to assure a concentric finish. Finished seats should be checked with a dial indicator and runout should not exceed .001".

To remove an insert (if a suitable puller is not available), drill two holes at opposite sides of the insert but not all the way through. Then cut through the undrilled portion with a sharp chisel and remove the two pieces.

To install a new insert, first remove all burrs and sharp edges from the seat recess. Then chill the new insert with "dry ice" to obtain maximum contraction of the metal and place it in the recess. If necessary, the insert may be pounded in by using a round driver the same size as the insert and pounding on same with a hammer.

If a standard insert is too loose, an oversize insert should be used. Oversize inserts are $\frac{1}{16}$" larger than the standard and, therefore, the recess should be bored out $\frac{1}{16}$" to accommodate the oversize insert.

When installed, peen the block or head around the insert bore to insure it remaining in place.

VALVE SPRINGS

All Engines

After removing the valve springs, wash them with gasoline or other suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring testing fixture if one is available. If a fixture is not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications given in the *Tune Up & Valve Specifications* table within 10% should be replaced. Likewise, any spring that stands shorter than the new spring used for comparison should be discarded. Of course, cocked springs should be scrapped.

VALVE GUIDES, REPLACE

All Engines

Clean the valve guides with a wire guide brush and check the clearance between the valve stems and guides. Excessive clearance will cause improper seating and burned valves. When there is too much clearance between intake valve stems and guides, there is a tendency to draw oil vapor through the guide on the suction stroke, causing excessive oil consumption, fouled spark plugs and poor low speed performance.

To check valve stem-to-guide clearance, take a new valve and place it in each valve guide and feel the clearance by moving the valve stem back and

Fig. 4 Valve timing marks. All engines

forth. If this check shows excessive clearance, it will be necessary to replace the valve guide.

If the clearance is not excessive when checking with a new valve but is excessive when checked with the old valve, the old valve stem is worn and a new valve must be installed.

Valve stem-to-guide clearance may also be checked with a dial indicator or with plug gauges.

Valve guides may be removed and installed with a suitable puller and installer made for the purpose. If such equipment is not available, the old guides can be driven out or they can be pulled out by using a piece of pipe together with a long bolt and suitable washers.

After the new guides have been installed, they should be reamed to round out the holes and to provide adequate operating clearances.

VALVE LIFTERS

All Engines

Valve lifters of the mushroom type are used in overhead valve engines, whereas barrel type lifters are used in L-head engines.

If a lifter face scores from too close an adjustment, or if breakage results, replace the defective unit with a new one.

TIMING GEARS

All Engines

For correct valve timing, timing gears should be assembled as shown in Fig. 4. Always use suitable puller and pusher equipment when servicing gears. This is particularly important in the case of the camshaft gear as there is danger of loosening the welch plug in back of the camshaft if the gear is driven on with hammer blows.

CAMSHAFT & BEARINGS

All Engines

Camshaft end play is controlled by a thrust plate bolted to the front face of the cylinder block behind the camshaft gear. End play should be held between .004″ and .008″. If the end play is excessive, install a new thrust plate.

Camshaft bearings should be installed in sets and care must be exercised to see that the oil holes in the bearings and the oil feed holes in the block are aligned to insure adequate lubrication.

After installing new camshaft bearings, they should be line-bored to round out the holes and to provide a running clearance of .0015-.0025″.

PISTONS & RODS, REMOVE

All Engines

After removing the cylinder head and oil pan, examine the cylinder bores above the ring travel area. If the bores are worn so that a ridge exists at this point, remove the ridge with a ridge reamer to avoid damaging rings or cracking ring lands of pistons during removal.

Before removing pistons, mark the pistons with a file on the inside of the skirt to indicate the bore from which each piston was removed and also its position in the bore with relation to the camshaft side of the engine. Connecting rods should also be suitably marked if they are not marked already.

Remove the connecting rod caps and push the assemblies out of the cylinders, using care to prevent rod bolts from nicking crankshaft journals. It is advisable to install caps on rods as they are removed to avoid mixing parts.

PISTONS & RODS, ASSEMBLE

All Engines

If the pistons and rods have factory markings to indicate their position in the cylinders, assemble and install them according to these marks, or according to the marks made during removal if they were not otherwise marked.

PISTONS, REPLACE

All Engines

Before a honing or boring operation is started, measure all new pistons with a micrometer at points 90 degrees away from the piston pin. Then select the smallest piston for the first fitting. The slight variation usually found between pistons in a set may provide for correction in case the first piston is fitted too free.

It is important that refinished cylinder bores are trued up to have not more than .0005″ out-of-round or taper. Each bore must be final honed to remove all stone or cutter marks and provide a smooth surface. During final honing, each piston must be fitted individually to the bore in which it will be installed and should be marked to insure correct installation.

After final honing and before the piston is checked for fit, each bore must be thoroughly washed to remove all traces of abrasive and then dried thoroughly. The dry bore should then be brushed clean with a power-driven fibre brush.

Both the piston and cylinder block must be at room temperature (70°) when the piston is checked for fit in the bore. Therefore, the cylinder should be allowed to cool after boring or honing and before the piston fit is checked. This is important because a difference of 10° between the temperature of parts is sufficient to produce a variation of .0005″.

With the piston rings and pin removed and cylinder wall and piston dry and clean, insert the piston upside down in the bore. Use a feeler ½″ wide which is long enough to extend the full length of the piston. The thickness of the feeler should be the same as the clearance given in the *Pistons, Rings & Bearings* table. With the feeler hooked to a spring scale, a pull of 5 to 10 lbs. should be required to pull the feeler past the piston.

PISTON RINGS, REPLACE

All Engines

When new rings are to be installed without reboring cylinders, the glazed cylinder walls should be slightly dulled but without increasing the diameter of the bore. This is done with a "Glazebuster" or a hone equipped with the finest grade of stones.

New rings must be checked for clearance in piston grooves and for gap in cylinder bores. The latter operation must be measured with the ring about two inches from the bottom of the cylinder bore to which it is to be fitted. Cylinder bores and piston grooves must be clean, dry and free from carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land and a false measurement of clearance will result.

If the piston grooves have worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of the new rings and ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

PISTON PINS, REPLACE

All Engines

To fit a pin in an aluminum piston, heat the piston in a pail of boiling water for several minutes. Then remove the piston and quickly insert the pin. A good fit is one which requires a light push of the thumb to insert the pin.

For 38B engines with cast iron pistons, a good fit is one which requires a light push with the palm of the hand to insert the pin with both parts at normal room temperature.

Fig. 5 Typical ball bearing type water pump

Fig. 6 Zenith 63 Series carburetor

Fig. 7 Float setting. Zenith 63 Series carburetor

Fig. 8 Zenith governor adjustments

ROD BEARINGS, REPLACE

All Engines

Rod bearings consist of two half shells. When the bearings are placed in the rod and cap the ends extend slightly beyond the parting faces so that when the rod bolts are tightened, the bearings will be clamped tightly in place to insure positive seating and prevent turning. *The ends of these bearings must never be filed flush with the parting surface of the rod and cap for the above reasons.*

Service bearings are provided in standard sizes and several undersizes, including undersizes for reground crankshafts.

After installing new bearings, the oil clearance may be checked with Plastigage which is available at any auto parts jobber. Full instructions for its use are furnished with the envelope in which it is contained.

MAIN BEARINGS, REPLACE

All Engines

Main bearings are the insert type, requiring no reaming or scraping. They may be removed and replaced without removing the crankshaft.

Plastigage may be used to check bearing clearance and instructions for its use are contained in the package.

CRANKSHAFT END PLAY, ADJUST

All Engines

End play of the crankshaft is regulated by a removable collar just to the rear of the crankshaft timing gear. There is a shim pack between the collar and the front main bearing. Excessive clearance may be reduced by removing the right number of shims.

Crankshaft end play limits are .004-.008" on L-head engines and from .005-.010" on overhead valve engines.

OIL PUMP REPAIRS

All Engines

Conventional gear type oil pumps, located in the crankcase, are used on all engines. After removing the oil pan, the pump may be unfastened from its mounting and disassembled for repairs.

Inspect the pump gears for nicks or burrs. Inspect the bottom cover for wear and dress down on a surface plate with emery if necessary. Place the bottom cover on the pump and check the drive shaft end play. If end play is excessive (more than .006"), replace the drive and idler gears.

WATER PUMP REPAIRS

All Engines

The water pumps used on these engines are of the ball bearing type with sealing accomplished by a non-adjustable spring-loaded seal, Fig. 5. In servicing these pumps, note carefully the arrangement of the seal parts as they are removed so that the new seal may be assembled correctly.

After disassembly, inspect the face of the pump body against which the sealing washer turns. Surface should be smooth and free from scores. Reface if necessary. Discard the pump impeller if it is corroded or loose on the shaft.

IGNITION TIMING

If a timing light is to be used to set ignition timing, disconnect the vacuum advance pipe to the carburetor and place a piece of tape over open end of pipe. *This is important as carburetor trouble can affect timing adjustments.*

Lacking a power timing light, an accurate method of setting ignition timing with the engine stopped is with the aid of a jumper light. Be sure to use a light bulb that corresponds with the system voltage of the vehicle.

1. Remove distributor cap and rotor and see that the breaker gap is set according to specifications.
2. Rotate engine until No. 1 cylinder is at the ignition timing point as indicated by the timing pointer and timing mark being lined up with each other.
3. Connect the jumper light between distributor ignition terminal and ground.
4. Turn on ignition switch.
5. Loosen distributor and turn it in the direction of normal rotation until the points just close (light out). Then slowly turn distributor in the opposite direction just to the exact point that the light goes on. Tighten distributor in this position.

CARBURETOR, ADJUST

Zenith 63 Series

Zenith 63AW-12, 63AW-14 and 63AW-16 models are used on these engines, Fig. 6. They are single barrel, updraft carburetors with a manifold vacuum-controlled power and accelerating system. A removable venturi tube measures the volume of air which passes through the carburetor.

Float Setting

Float height setting is measured from the gasket surface or parting line of the float chamber cover to the bottom of the float at the center, Fig. 7, with the fuel

inlet valve seated (holding float chamber cover upside down). This distance should measure $1\frac{19}{32}''$ on 63AW-12 carburetors and $2\frac{1}{64}''$ for 63AW-14 and 63AW-16 units.

Under three pounds fuel pump pressure the fuel level should measure $\frac{55}{64}''$ on 63AW-12 units and $1\frac{3}{64}''$ on 63AW-14 and 63AW-16 carburetors.

Idle Mixture

For a preliminary adjustment, turn the needle into its seat and open one full turn. Run the engine until it reaches normal operating temperature and alter the adjustment as required to obtain smooth performance. The range should be between 1 and 1½ turns open.

Accelerator Pump

This adjustment is provided in the form of three grooves on the pump piston rod. The carburetor must be opened up and the vacuum pump piston assembly removed. Compress the spring toward the vacuum piston to permit moving the pump rod to the outer end of the slot in the pump piston base. At this point the slot is wide enough to permit removal of the rod.

There are three grooves near the end of the pump rod providing for three lengths of pump stroke. Install the pump piston in the groove nearest the end of the rod to obtain minimum or a half stroke; in the center groove for intermediate stroke, and in the third groove for maximum stroke. The spring holds the rod in the center of the pump piston base.

CARBURETOR GOVERNOR

Zenith

To change the governed speed, remove the seal wire and large seal plug, Fig. 8. Turn the main adjusting screw clockwise to increase or counter-clockwise to decrease governed speed. If the governor does not show definite response to changes of ¼ to 1 full turn of the adjusting screw, it indicates a defective governor.

If the governor "surges" or "hunts" to a higher or lower engine speed, remove the small seal plug and turn the compensating spring adusting screw ¼ turn counter-clockwise until the surge is overcome.

If the governor does not respond quickly enough when governed speed is approached and the action "lags" or is "flat", turn the compensating adjusting screw clockwise until the symptom is overcome. Do not turn the adjustment more than ½ turn at a time without checking the performance of the vehicle on the road.

Clutch

LIPE-ROLLWAY TYPE ML

This clutch, Fig. 1, is a single plate, dry disc type in which pressure on the driven disc is provided by a heavy spiral spring acting through 20 interlocked levers.

Fig. 1 Lipe-Rollway Type ML multiple lever clutch

Clutch Adjustment

The original setting of the clutch provides for 1½" free movement of the clutch pedal. As the facings wear the clutch sleeve moves toward the clutch release bearing, reducing the clearance and automatically cutting down on the free travel of the clutch pedal. When this travel drops to about ½", the clutch should be readjusted.

Never wait for the clutch to start slipping before adjusting it. It may then be too late to make an adjustment. Clutch facings quickly disintegrate once they become burned through slippage, and both the facings and pressure plate are short lived thereafter.

Do not adjust the clutch pedal linkage until the clutch has been adjusted to the correct Dimension "A", Fig. 2. The correct Dimension "A" for the clutches used are as follows. *Clutches may be identified by the manufacturer's number stamped on a name plate or on the cover or flywheel ring.*

Clutch No.	Dimension "A"	Shims Req. ①
130-1-320	$1\frac{1}{16}''$	6
130-1-029	$2\frac{1}{8}''$	6
130-1-319	$1\frac{1}{16}''$	6
140-1-293	$1\frac{1}{8}''$	6
140-1-308	$1\frac{5}{16}''$	6
140-1-332	$1\frac{5}{16}''$	7
140-1-509	$1\frac{3}{8}''$	7 or 8
150-1-295	$1\frac{3}{16}''$	7
150-1-301	$1\frac{3}{16}''$	7
150-1-465	$1\frac{3}{16}''$	7
150-1-466	$1\frac{3}{16}''$	8

①Removal of one shim .015" thick is equivalent to reducing Dimension "A" by $\frac{3}{32}''$. The number of shims listed for each clutch should be placed under each strap when overhauling the clutch.

1. To adjust the clutch, block the clutch pedal in the depressed position. This is important, otherwise the straps and studs may become bent.
2. Back off adjusting nuts five full turns.
3. Remove pedal block. This will allow the adjusting plate to move out of contact with the adjusting shims.
4. Remove a sufficient number of shims to obtain Dimension "A". It

Fig. 2 Adjusting points on Lipe-Rollway Type ML clutch

is usually sufficient to remove only one shim from each stud, Fig. 3, then checking Dimension "A" before removing more. *Be sure no portion of the shim is torn and remains under the flange of the adjusting plate and that an equal number of shims remain under each strap.*

Fig. 3 Removing shims to establish Dimension "A"

5. Reblock the clutch pedal. This moves the adjusting plate into contact with the adjusting shims. Then tighten each adjusting strap nut firmly.
6. Recheck Dimension "A".
7. After the correct Dimension "A" has been established, adjust the vehicle clutch release linkage so as to obtain proper release bearing clearance or 1/8" to 5/32" as indicated in Fig. 4.

Clutch Driven Disc, Replace

1. After removing the transmission remove the cap screws holding the clutch to the flywheel and remove the clutch and driven disc.
2. Remove the flywheel ring stud nuts and adjusting straps one at a time and place the correct number of shims (see table above) under each strap.
3. Examine flywheel, making sure friction face is clean, smooth and dry.
4. Check release bearing and pilot bearing to make sure they are in good condition. Both these bearings are factory sealed and require no further lubrication.
5. Install a new driven disc and bolt the clutch to the flywheel, using a spare splined shaft to align the disc. When bolting the flywheel, screw in each bolt until it just contacts the cover plate, then gradually tighten alternate bolts until the clutch is drawn up evenly against the flywheel. Tighten remaining clutch-to-flywheel bolts.
6. After clutch is installed, check for proper release. Adjust clutch and pedal linkage as outlined above.

Fig. 4 Checking clearance between clutch release bearing and sleeve. Clearance should be 1/8" to 5/32" and is obtained by adjusting vehicle clutch linkage

Pressure Plate, Replace

A pressure plate dished in excess of .015" or badly scored should be replaced with a new part. After removing the transmission and the clutch from the flywheel, proceed as follows:

1. Place clutch on arbor press with pressure plate down and compress spring as far as possible.
2. Remove four retractor springs after first removing pins.
3. Slowly release arbor press, allowing clutch spring to return to normal position.
4. Holding clutch assembly together by hand, turn it over and carefully lift off pressure plate.
5. Install new pressure plate, turn clutch assembly over and compress in arbor press.
6. See that retractor springs are in place and install pins.
7. Remove clutch from press and reinstall on flywheel.

Transmissions & Rear Axles

For Clark, Fuller, New Process, Spicer and Warner Transmissions used on Brockway trucks, see the "name" chapters for service procedures and lubricant capacities.

For Eaton and Timken (Rockwell-Standard) driving axles used on Brockway trucks, see the "name" chapters for service procedures and lubricant capacities.

Steering Gear Section

ROSS CAM & LEVER

This steering gear, Fig. 1, is the cam and twin lever type in which the cam is mounted on ball bearings and the lever shaft turns on steel backed bronze bushings.

As the cam is turned by the wheel tube, the follower studs are pulled along the cam groove causing the lever arm to rotate the lever shaft. As an aid to easy steering the lever shaft studs which engage the cam are mounted on tapered roller bearings. The groove in the cam is cut shallower in the straight-ahead driving position to provide closer adjustment between the studs and the cam where most of the steering action occurs.

Fig. 1 Ross cam and lever twin lever mounted steering gear

Cam End Play, Adjust

1. Free the steering gear of all load by disconnecting the drag link and loosening the steering column braces.
2. Loosen the lock nut and adjusting screw in the side cover to free the studs in the cam groove.
3. Remove the upper cover stud nuts and raise the housing upper cover to permit removal of the adjusting shims, which are .002″, .003″ and .010″ thickness.
4. Clip and remove one thin shim, tighten down the cover and check the adjustment. There should be a slight drag but the steering wheel should turn freely with the thumb and forefinger lightly gripping the rim. If necessary, remove or replace shims until the adjustment is correct.

Lever Shaft Backlash, Adjust

1. Centralize the steering gear by turning the wheel all the way to the right. Then starting from this point count the number of turns required to reach end of travel to the left. Turn the wheel back half this number of turns to the mid-position.
2. Tighten the side cover adjusting screw until a very slight drag is felt through the mid-position when turning the steering wheel slowly from one side to the other. The gear should not bind in any position but a slight drag should be felt in the mid-position only.
3. After proper adjustment is secured, tighten lock nut and give the gear a final check for binding.

Stud Roller Bearing, Adjust

In most cases the foregoing adjustments will be adequate but it is sometimes necessary to adjust the stud roller bearing units as they should be preloaded at all times. A heavy drag should be felt when revolving the studs by hand. If a torque wrench is available the bearings should be adjusted so that the torque required to revolve the stud is as follows:

Lever Shaft Dia.	Torque, In. lb.
1⅜″	3-4
1½″	3-4
1⅝″	4-8
1¾″	5-11

1. To adjust, remove lever shaft from housing, wash the bearings in solvent and blow dry with compressed air, using care not to spin the bearings. Lubricate the bearings with light oil.
2. Straighten out the prong of the locking washer to release the stud nut. Remove the nut and install a new locking washer.
3. While holding the stud nut from turning with a spanner wrench on the locking washer, tighten the nut as required to revolve the stud in accordance with the table above.
4. When proper adjustment has been secured, bend the prong of the washer against a side of the nut to keep it from turning.
5. Lubricate the bearings with gear oil and assemble the lever shaft in the steering gear housing.

ENGINE TIGHTENING SPECIFICATIONS★

★Torque specifications are for clean and lightly lubricated threads only. Dry or dirty threads produce increased friction which prevents accurate measurement of tightness.

(1)—Cylinder numbering (front to rear): Left bank 1-3-5-7, right bank 2-4-6-8.
(2)—Valve seat: intake 31°, exhaust 46°. Valve face: intake 30°, exhaust 45°.
(3)—For 1/2 ton and 1 ton models .013H. For 1 1/2 and 2 ton .020H.
(4)—New points .019", used points .016".
(5)—Tighten rocker arm stud nut until all lash is eliminated, then turn stud nut the additional turns listed.
(6)—Cylinder numbering (front to rear): Right bank 1-3-5-7, left bank 2-4-6-8.
(7)—First short radial mark clockwise from timing ball.
(8)—With distributor vacuum line disconnected and opening in manifold closed.
(9)—C44 for 1/2 to 1 1/2 ton models, 43-5 for 2 ton models.
(10)—C45 for 1/2 to 1 1/2 ton models, C43 for 2 ton models.
(11)—C45 for 1/2 to 1 1/2 ton models, C42-1 for 2 ton models.
(12)—AC. Normal service.
(13)—Set timing on No. 2 cylinder for Step Van models, using timing pointer at front of oil pan. Also disconnect distributor line and plug opening.

Engine Section

V8-348 and 409 engines

ENGINE, REPLACE

All engines, except for the following items, are removed from the chassis in the conventional manner:

1. On Step Van models, it is necessary to remove the engine box, driver's seat and floor panel between stepwells (P20 and P30 only). Also remove floor pan around steering column and pedals.
2. On Low Cab Forward models, remove front end sheet metal.
3. Vehicles with 4-153, 6-230 and 6-292 engines with stick shift transmission, remove transmission before lifting out engine. With automatic transmission, remove engine separately from transmission, leaving transmission in vehicle. Be sure to secure converter in transmission with a retaining strap to prevent it from falling out when engine is removed.
4. On 6-235, 6-261 and all V8's remove engine and transmission together.

CYLINDER HEAD, REPLACE

4-153, 6-230, 6-292 Engines

1. Remove necessary access covers depending on vehicle being serviced.
2. Drain cooling system and remove air cleaner.
3. Disconnect choke cable, accelerator pedal rod at bellcrank on manifold, and fuel and vacuum lines at carburetor.
4. Disconnect exhaust pipe at manifold flange, then remove manifolds and carburetor as an assembly.
5. Disconnect wire harness from temperature sending unit and coil, leav-

ing harness clear of clips on rocker arm cover.
6. Disconnect radiator hose at water outlet housing and battery ground strap at cylinder head.
7. Remove spark plugs. On 6-cylinder engines, remove coil.
8. Remove rocker arm cover. Back off rocker arm nuts, pivot rocker arms to clear push rods and remove push rods.
9. Unfasten and remove cylinder head.
10. Reverse removal procedure to install and tighten head bolts to the specified torque and in the sequence shown in Figs. 1 and 2.

6-235, 6-261 Engines

1. Drain radiator, raise hood, remove air cleaner.
2. Disconnect choke and throttle wires from carburetor if engine is so equipped.
3. Remove lower end of throttle rod from bell crank and disconnect throttle return spring.
4. Disconnect gasoline and vacuum lines from carburetor. If equipped with two-speed axle and/or Hydro-vac, disconnect vacuum line from manifold fitting.
5. Remove gasoline and vacuum line retaining clip from water outlet.
6. Unfasten and remove manifold assembly from cylinder head.
7. Remove intake manifold pilot sleeves.

Engine oiling system. 6-235, 6-261 engines

Engine oiling system. V8-283, 327 engines

Engine oiling system. V8-348, 409 engines

8. Disconnect radiator hose from water outlet, remove outlet-to-cylinder bolts and remove outlet and thermostat.
9. If so attached, remove battery ground strap-to-cylinder head bolt.
10. On engines with positive crankcase ventilation, remove air cleaner attachment to rocker arm cover.
11. Remove rocker arm cover.
12. Remove all spark plugs.
13. Remove ignition coil.
14. Remove temperature indicator element from cylinder head.
15. Remove rocker arm assembly.
16. Remove push rods and valve lifters.
17. Unfasten and remove cylinder head.
18. Reverse removal procedure to install and tighten head bolts to the specified torque and in the sequence shown in Figs. 3 and 4.

Fig. 1 Cylinder head tightening sequence. 4-153 engine

V8-265, 283, 327

1. Drain radiator and remove air cleaner and crankcase ventilator.
2. Disconnect choke and throttle rod from carburetor.
3. Disconnect fuel and vacuum from carburetor.

Fig. 2 Cylinder head tightening sequence. 6-230, 6-292 engines

4. Remove distributor.
5. Remove spark plugs.
6. Remove water outlet hose and heater hose from intake manifold.
7. Remove temperature indicator unit from intake manifold.
8. Remove intake manifold.
9. Remove fan belts.
10. Disconnect exhaust manifold from cross-over pipe and allow cross-over to drop for clearance.
11. Remove heat control valve from right bank exhaust manifold.
12. Remove generator.
13. Remove exhaust manifolds.
14. Remove rocker arm covers.
15. Back off rocker arm nuts, pivot rocker arms to clear push rods and remove push rods.
16. Remove head bolts and lift off heads.

Installation

Reverse the foregoing procedure to install the head, observing the following:

1. Use a good head gasket paste with these steel gaskets.
2. Oil threads of all *long* head bolts. *Coat threads of all short head bolts with special sealing compound such as Permatex No. 3 as these bolts protrude into water passages and require this compound to prevent rusting.*
3. Install and tighten head bolts a little at a time in the order shown in Fig. 5.
4. When installing intake manifold, coat ends of side gaskets around water passages with gasket sealing compound. Tighten intake manifold bolts a little at a time.
5. When installing exhaust manifolds, coat end of gaskets around water passages with sealing compound, and exhaust manifold bolts with a graphite type grease.
6. After completing the installation, warm up the engine to operating temperature and re-torque cylinder head bolts. Then adjust valves.

V8-322 Engine

1. Drain cooling system.
2. Remove air cleaner and disconnect all pipes from carburetor and intake manifold.
3. Take off intake manifold and carburetor as an assembly.
4. When removing *right* cylinder head, remove generator mounting bracket.
5. When removing *left* cylinder head, disconnect temperature gauge wire.
6. Remove spark plug cover and disconnect wires from plugs.
7. Disconnect water manifold from both cylinder heads and disconnect exhaust manifold from head to be removed.
8. With air hose and cloths, clean dirt off cylinder head and adjacent area to avoid getting dirt into engine, and *particularly into the hydraulic valve lifters.*
9. When installing, tighten heads in the sequence shown in Fig. 6.

V8-348, 409

1. Remove air compressor and/or power steering pump if so equipped.

Fig. 3 Cylinder head tightening sequence. 1952

Fig. 4 Cylinder head tightening sequence. 1953-62 Six-cyl.

Fig. 5 Cylinder head tightening sequence. V8-265, 283, 327 engines

Fig. 6 Cylinder head tightening sequence. V8-322 engine

Fig 7 Cylinder head tightening. V8-348, 409

2. Drain radiator and remove air cleaner.
3. Disconnect choke and throttle linkage and fuel and vacuum lines from carburetor.
4. Disconnect wiring from engine as required.
5. Remove distributor and spark plugs.
6. Remove intake manifold and fan belt.
7. Remove exhaust manifolds.
8. If left head is to be removed take off generator.
9. Remove rocker arm covers.
10. Back off rocker arm nuts, pivot rocker arms to clear push rods and lift out push rods, noting that exhaust push rods are longer than intake rods.
11. Unfasten and lift off heads.
12. Reverse removal procedure to install heads and tighten them in the sequence shown in Fig. 7.

VALVE ARRANGEMENT

Front to Rear

4 Cylinder ..... E-I-I-E-E-I-I-E
6 Cylinder ..... E-I-I-E-E-I-I-E-E-I-I-E
V8's ..... E-I-I-E-E-I-I-E

VALVES, ADJUST

Hydraulic Lifters

The following procedure, performed with the engine running should be done only in case readjustment is required.

1. After engine has been warmed up to operating temperature, remove valve cover and install a new valve cover gasket on cylinder head to prevent oil from running out.
2. With engine running at idle speed, back off valve rocker arm nut until rocker arm starts to clatter.
3. Turn rocker arm nut down slowly until the clatter just stops. This is the zero lash position.
4. Turn nut down ¼ additional turn and pause 10 seconds until engine

Engine oiling system. 6-230, 6-292, 4-153 engines

runs smoothly. Repeat additional ¼ turns, pausing 10 seconds each time, until nut has been turned down the number of turns listed in the *Valve Specifications Chart* from the zero lash position.

Service Note

This preload adjustment must be done slowly to allow the lifter to adjust itself to prevent the possibility of interference between the intake valve head and top of piston, which might result in internal damage and/or bent push rods. Noisy lifters should be replaced.

1961 Service Note

There is an "Engine Date Stamp" located on a machined surface at the front of the cylinder block which denotes the month and day on which the engine was assembled.

V8 engines assembled on and after 1/23/61 (date stamped F-0123) and 1/30/61 (stamped T-0130) are equipped with short travel lifters similar to those used in 1960 and earlier models. Engines assembled before these dates have long travel lifters. Be sure to check the date stamp before adjusting valves on 1961 V8 engines.

Mechanical Lifters

With the engine warmed to operating temperature as described above, turn rocker arm stud nut or adjusting screw as required to obtain the clearances given in the *Valve Specifications* table.

Service Note

To be sure that the valves and lifters function perfectly, it is strongly recommended that a vacuum gauge be used when making the adjustment on hydraulic lifter jobs. With vacuum gauge connected and engine idling, tighten each rocker arm nut until the *highest and steadiest vacuum is indicated on the gauge.*

ROCKER ARM STUDS

Rocker arm studs that have damaged threads may be replaced with standard studs. Loose studs should be replaced with .003″ or .013″ oversize studs which are available for replacement.

Remove the old stud by placing a suitable spacer over the stud, Fig. 8. Install a nut and flat washer on the stud and pull out the stud by turning the nut. After reaming the hole for an oversize stud, coat the press-fit area of the new stud with rear axle lubricant. Install the stud by driving it in until it protrudes from the head the same distance as the other studs, Fig. 9.

PUSH RODS

1962-63 Service Note

When a replacement push rod has a paint stripe at one end, this painted end must be installed in contact with the rocker arm. To provide durability a hardened insert is incorporated in the rocker arm end of these push rods.

V8-265, 283 and 327 engines

On both the 348 and 409 engines, the exhaust valve push rods are longer than the inlet valve push rods used in these engines.

ROCKER ARMS

1952-62 Sixes

Sludge and gum formations in the rocker arms and shafts will restrict the normal flow of oil to rocker arms and valves. Each time the rocker arm and shaft assemblies are removed they should be disassembled and thoroughly cleaned.

1. Remove support bolts, hairpin locks, springs, rocker arms and supports, Fig. 10.
2. Clean all sludge and gum formation from the inside and outside of the shafts.
3. Clean oil holes and passages in the shafts and rocker arms.
4. Clean rocker arm oil collector.
5. Inspect shafts for wear. Check fit of rocker arms on shafts and check valve end of rocker arms for excessive wear. Replace all worn parts.

Service Note

There are three each of eight different type rocker arms used—right and left-hand exhaust and right and left-hand intake. They must be installed on the shafts in the correct position. For identification, each type rocker arm carries a different number stamped on the side. The proper locations of the rocker arms according to number are as follows:

For 216 and 261 Engines

No. on Rocker	Type Rocker Arm	For Cylinder No.
1	L.H. Exhaust	1-3-5 Exhaust
2	R.H. Exhaust	2-4-6 Exhaust
5	L.H. Intake	2-4-6 Intake
6	R.H. Intake	1-3-5 Intake

Fig. 8 Removing valve rocker stud

Fig. 9 Installing valve rocker stud

Fig. 10 Layout of rocker arm and shaft parts. 1952-62 Sixes

For 235 Engines

No. on Rocker	Type Rocker Arm	For Cylinder No.
9	L.H. Exhaust	1-3-5 Exhaust
0	R.H. Exhaust	2-4-6 Exhaust
3	L.H. Intake	2-4-6 Intake
4	R.H. Intake	1-3-5 Intake

One end of each rocker arm shaft is plugged; the open end of each shaft must be toward the center.

V8-322 Engine

The eight rocker arms for each bank of cylinders are mounted on a tubular steel shaft supported on the cylinder head by four brackets. The rocker arms are offset to accommodate the different planes of movement of the valves and the push rods which pass through the cylinder head to one side of the valves.

Note that the rocker arm and shaft assemblies are identical and interchangeable. The four rocker arms on each end of the shaft are offset toward the middle of the shaft so that no special markings are required for proper assembly.

A small notch cut in one end of the rocker arm shaft must be upward, and this end of the shaft must be toward the front of the engine on the right bank and toward the rear of the engine on the left bank. Assembling the shaft to rocker arms with the notch placed as specified will place the oil holes in the shaft in the proper relationship to the rocker arms.

VALVES, REMOVE

1. Remove the cylinder head as previously outlined and place it on a work bench.
2. With a suitable valve spring compressor, Fig. 11, compress the valve springs and remove valve keys, spring caps, oil seals and springs.
3. Remove exhaust valve rotators on engines so equipped.
4. Remove valves from cylinder head and place them in a board with numbered holes so they can be identified as to the valve port from which they were removed.

Fig. 11 Use of valve spring compressor tool

Caution

V8-348 engines are equipped with exhaust valves filled with sodium for cooling purposes. When handling these valves, follow these precautions:

1. Never cut open an old valve and be extremely careful when removing a broken valve from an engine. Otherwise, the metallic sodium in the valve may contact and burn the skin.
2. Bury discarded sodium-cooled valves in some inaccessible place to prevent other persons from handling them. *Never immerse one of these valves in water.*

V8 Engines

Place the cylinder head on its side and, with a suitable valve spring compressor, compress the valve spring and remove the valve locks. Release the tool and remove spring retainer, the valve baffle on intake valves, and seal from valve stem. Repeat operation on each valve.

Remove valves from head and place them in a board with numbered holes so they will be in proper sequence for inspection and assembly.

Remove rocker arm nuts, lift rocker arms off studs and remove pivot balls from rocker arms.

Clean all carbon from combustion chambers, valve ports, valve bores, push rods (inside and outside), valve stems and heads, and deposits from pistons and cylinders.

VALVES, GRIND

4 & 6 Cylinder Engines

In refacing valves, take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced.

Inspect the valve seats in the head for cracks, burns, pitting, ridges or improper angle. During any general engine overhaul, it is advisable to reface the valves seats regardless of their condition. If new valve guides are required, they must be installed before refacing the seats if the equipment used has a valve guide pilot.

The valve seat width after refacing should measure $\frac{1}{16}$" to $\frac{3}{32}$" except exhaust valve on 261 engine which should be $\frac{3}{32}$" to $\frac{1}{8}$". The width may be checked by placing a scale across the face of the valve seat.

A simple check can be made to prove the fit of the valve in the valve seat. Make pencil marks about $\frac{1}{4}$ in. apart across the valve face, place the valve in its guide and give the valve $\frac{1}{2}$ turn in each direction while exerting firm pressure on the valve head. Remove the valve and, if all pencil marks have not been removed at the point of contact with the valve seat, it will be necessary to repeat the refacing operation and again check for proper seating.

V8 Engines

Clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads as well as the gum which might have accumulated on the stems.

In refacing valves take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced. This condition leads to premature breakage, burning and pre-ignition due to heat localizing on this knife edge. If the edge of the valve head is less than $\frac{1}{32}$" thick after grinding, replace the valve.

Inspect the valve seats in the head for cracks, burns, pits, ridges or improper angle. Reconditioning the valve seats is very important because the seating of the valves must be perfect for the engine to deliver the power and performance built into it. Another important factor is the cooling of the valve heads. Good contact between each valve and its seat in the head is imperative to insure that the heat in the valve head will be properly carried away.

Regardless of the methods for valve seat reconditioning, the final seat for the valves should be $\frac{1}{16}$" to $\frac{3}{32}$" except exhaust valves on 348 engine, Taskmaster and Super-Taskmaster engines which should be $\frac{3}{32}$" to $\frac{1}{8}$". Seats shoud be concentric within .002" as indicated on dial gauge, Fig. 12.

Fig. 12 Checking valve seat concentricity with dial gauge

Fig. 13 Use of valve spring tension gauge

VALVE SPRING TESTING

After washing the springs in gasoline or other solvent, examine them for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring pressure on a spring testing fixture if one is available, Fig. 13. If not, at least check the free length of each spring by standing it alongside a new one. Any spring that does not conform to the pressure specifications given in the *Valve Data* table within 10% should be replaced. Likewise, any spring that stands up shorter than the new spring used for comparison should be discarded.

VALVE SPRING INSTALLED HEIGHT

When valves and seats are reground the position of the valve in the head is changed so as to lessen the valve spring tension. Without proper spring tension the valve does not seat long enough or it may not seat completely. Since the valve is cooled by transferring the heat from the valve head to the seat and thence to the coolant, improper valve spring tension will cause worn, pitted and distorted valves which result in loss of compression and power as well as poor gasoline mileage.

When valves, springs, retainers and locks are installed, measure the assembled height of the valve springs from the surface of the cylinder head spring pad to the underside of the spring retainer as shown in Fig. 14. If the assembled height is greater than the dimension given in the *Tune Up and Valve Specifications Chart,* install a spacer or shim of proper thickness between cylinder head spring pad and spring to bring the assembled height to specifications.

Do not install spacers unless necessary. Excessive use of spacers will result in overstressing valve springs and overloading camshaft lobes which could lead to spring breakage and worn camshaft lobes.

GRINDING VALVE STEMS

For Proper Lifter Clearance

If a valve grind job is needed, and if shims are found under the valve springs, very likely the valves, if reground, would not leave sufficient margin on the valve head for satisfactory operation. Since the maximum thickness of shimming that can be used satisfactorily is 1/16" and since the acceptable valve head margin is approximately $\frac{1}{16}$" to $\frac{3}{32}$", one can readily see that there would be insufficient margin left on the valve head if it was reground. Therefore, it is recommended that new valves be installed.

After grinding the valves, if shims are required to restore the correct valve spring installed height, the valve stem should be ground off the same amount as the thickness of shims required. This will automatically provide the proper static clearance between the hydraulic lifter and the push rod.

VALVE GUIDES, REPLACE

1952-62 Six & V8-322 Engine

Clean the valve guides with a wire guide brush, and clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads, as well as the gum which might have accumulated on the stems.

Excessive clearance between valve stems and guides will cause improper seating and burned valves. When there is too much clearance between intake valve stems and guides, there is a tendency to draw oil vapor through the guide on the suction stroke, causing excessive oil consumption, fouled spark plugs and poor low speed performance.

Valve stem-to-guide clearance may be checked with special "GO" and "NO-GO" gauges. Lacking these, an alternate method is to take a new valve and place it in each valve guide and feel the clearance by moving the valve stem back and forth. If this check shows excessive clearance, it will be necessary to replace the guides that are worn as indicated by this test. If the clearance is not excessive when checking with a new valve but is excessive when checked with the old valve, it is an indication that the old valve stem is worn and a new valve must be installed.

To remove the old guides, place the cylinder head on the table of an arbor press and, with a suitable piece of round stock, press out the guides.

Special drivers having stop collars are available to install the new guides to the correct position. Lacking these tools, install the guides so they are positioned as shown in Figs. 15, 16 and 17. After the guides are installed, they should be finish reamed with hand reamer.

Fig. 14 Checking installed height of valve spring

Fig. 15 Valve guide location. 1952-53 216 engine

Fig. 16 Valve guide location. 1952-53 253 six-cyl.

Fig. 17 Valve guide location. 1954-55 235 six-cyl. engine. For the 1956-62 235 and 261 six-cyl. engines, locate intake guide 1" and exhaust guide 15/16"

Fig. 18 Hydraulic valve lifter

V8-265, 283, 327, 348, 409

Valves operate in guide holes bored directly in the cylinder head. When valve stem-to-guide clearance becomes excessive, valves with oversize stems of .003", .015" and .030" are available for service replacement. When necessary to install valves with oversize stems the valve bores should be reamed to provide the clearance given in the *Tune Up and Valve Specifications* chart.

Check the valve stem clearance of each valve (after cleaning) in its respective valve guide. If the clearance exceeds the service limits of .004" on the intake or .005" on the exhaust, ream the valve guides to accommodate the next oversize diameter valve stem.

Standard valve stem diameters for these engines are as follows:

Engine	*Intake*	*Exhaust*
V8-265	.3415-.3422"	.3410-.3417"
283 (57-61)	.3415-.3422"	.3410-.3417"
348 (1958)	.3145-.3422"	.4335-.4345"
348 (59-61)	.3415-.3422"	.3710-.3717"
283 (62-63)	.3710-.3417"	.3410-.3417"
327	.3710-.3417"	.3410-.3417"
348 (62-63)	.3712-.3722"	.3705-.3717"
409	.3712-.3722"	.3705-.3717"

Fig. 20 Installing timing case cover. 4-153, 6-230, 6-292 engines

HYDRAULIC VALVE LIFTERS

The hydraulic valve lifters used in models with Powerglide, Fig. 18, are simple in design, readjustments are not necessary and servicing them requires that care and cleanliness be exercised in the handling of parts.

The easiest method for locating a noisy valve lifter is by the use of a piece of garden hose approximately 4 feet in length. Place the end of the hose near the end of each intake and exhaust valve with the other end of the hose near the ear. In this manner, the sound is localized, making it easy to determine which lifter is at fault.

Another method is to place a finger on the face of the valve spring retainer. If the lifter is not functioning properly, a distinct shock will be felt when the valve returns to its seat.

In most cases where noise exists in one or more lifters, all lifter units should be removed and cleaned. If dirt, varnish, carbon, etc. is found to exist in one unit, it more than likely exists in all the units.

Plungers are not interchangeable as they are selectively fitted at the factory. Should a plunger or lifter body become damaged, it is necessary to replace the entire unit.

The plunger must be free in the lifter body. A simple test for this is to be sure the plunger will drop of its own weight in the body. There must be no excessive leakdown and there must be no ball check valve leakage.

Valve lifters should be placed in a rack in their proper sequence so they can be installed in the original locations in the block.

Disassemble & Assemble

1. Hold plunger down with push rod and, using a small screw driver or awl, remove plunger retainer.
2. Remove parts from lifter body.
3. Clean all parts and inspect for damage. If any parts are damaged, the entire lifter assembly should be replaced. The inertia valve in the plunger for rocker arm lubrication should move when the plunger is shaken.
4. To reassemble, invert plunger and set ball into hole in plunger. Place ball check valve retainer over ball and on plunger. Place check valve retainer spring over retainer. Assemble body over plunger assembly. Turn assembly over and install push rod seat. Compress plunger with push rod and install retainer.
5. Compress plunger to open oil holes and fill plunger with SAE 10 oil. Work plunger up and down and refill.

TIMING CASE COVER

4-153, 6-230, 6-292 Engines

1. To remove cover, remove radiator.
2. Remove vibration damper (6-cyl.) or pulley (4-cyl.).
3. Remove oil pan
4. Unfasten and remove cover.

Fig. 19 Timing gear oil nozzle removal. 4-153, 6-230, 6-292 engines

5. Pry oil seal out of cover with a large screwdriver. Install new seal with open side of seal inside of cover and drive or press seal into place.
6. If oil nozzle is to be replaced, remove it with pliers as shown in Fig. 19. Drive new nozzle in place, using a suitable light plastic or rubber hammer.
7. Clean gasket surfaces.
8. Install a suitable centering tool over end of crankshaft.
9. Coat gasket with light grease and stick it in position on block.
10. Install cover over centering tool, Fig. 20, and install cover screws, tightening them to 6 to 8 ft. lbs. *It is important that the centering tool be used to align the cover so the vibration damper installation will not damage the seal and position seal evenly around damper hub surface.*

1952-62 Six

Before installing the timing gear cover, be sure that the oil seal is seated properly in its recess in the cover, otherwise premature wear of the seal will result, causing an oil leak.

When replacing the cover, use a sleeve

Fig. 21 Use of timing gear cover centering sleeve. 1952-62 Six

Fig. 22 Removing camshaft gear. 4 and 6 cylinder

Fig. 23 Checking camshaft end play. 4 and 6 cylinder

Fig. 24 Using puller to remove crankshaft gear. 4 and 6 cylinder

which is the same size as the hub of the vibration damper, Fig. 21, slipping it over the front end of the crankshaft to act as a guide when replacing the cover.

Apply a light film of grease on the inner circumference of the seal to prevent it from being damaged when the vibration damper is being installed.

V8-265, 283, 327, 348, 409

To remove the cover, take off vibration damper and remove oil pan. Remove heater hose from water pump, and water pump from cylinder block. Unfasten and remove cover from engine.

When installing the cover, make certain that the oil slinger is in place against the crankshaft sprocket. Coat the oil seal with light grease and, using a new cover gasket, install cover and gasket over dowel pins in cylinder block.

V8-322 Engine

To remove the cover, drain cooling system, then remove radiator, shroud, fan belt, fan, pulley and vibration damper. Remove all bolts that attach the cover and water manifold to upper and lower crankcase and cylinder heads. *Do not remove five small bolts attaching water pump to cover.* Remove cover and manifold, using care to avoid damaging oil pan gasket.

When installing the cover, install oil slinger on crankshaft with concave side outward and reinstall all parts by reversing the procedure for removal.

TIMING GEARS

4 & 6 Cylinder Engines

When necessary to install a new camshaft gear, the camshaft will have to be removed as the gear is a pressed fit on the shaft. The camshaft is held in position by a thrust plate which is fastened to the crankcase by two capscrews which are accessible through two holes in the gear web.

Use an arbor press to remove the gear and when doing so, a suitable sleeve, Fig. 22, should be employed to support the gear properly on its steel hub.

Before installing a new gear, assemble a new thrust plate on the shaft and press the gear on just far enough so that the thrust plate has practically no clearance, yet is free to turn. The correct clearance is from .001″ to .005″, Fig. 23.

The crankshaft gear can be removed by utilizing the two tapped holes in conjunction with a gear puller, Fig. 24.

When the timing gears are installed, be sure the punch-marks on both gears are in mesh, Fig. 25. Backlash between the gears should be from .004″ to .006″, Fig. 26. Check the run-out of the gears, Fig. 27, and if the camshaft gear run-out exceeds .004″ or the crank gear run-out is in excess of .003″, remove the gear (or gears) and examine for burrs, dirt or some other fault which may cause the run-out. If these conditions are not the cause, replace the gear (or gears).

Fig. 25 Valve timing. 4 and 6 cylinder

Fig. 26 Checking timing gear backlash. 4 and 6 cylinder

Fig. 27 Checking runout of timing gears with dial indicator. 4 and 6 cylinder

TIMING CHAIN

V8-265, 283, 327, 348, 409

1. Remove timing chain cover as outlined previously.
2. Remove crankshaft oil slinger.
3. Crank engine until "O" marks on sprockets are in alignment, Fig. 28.
4. Remove three camshaft-to-sprocket bolts.
5. Remove camshaft sprocket and timing chain together. Sprocket is a

Fig. 28 Valve timing. V8-265, 283, 327, 348, 409

light press fit on camshaft for approximately 1/8". If sprocket does not come off easily, a light blow with a plastic hammer on the lower edge of the sprocket should dislodge it.

6. If crankshaft sprocket is to be replaced, remove it with a suitable gear puller. Install new sprocket, aligning key and keyway.
7. Install chain on camshaft sprocket. Hold sprocket vertical with chain hanging below and shift around to align the "O" marks on sprockets.
8. Align dowel in camshaft with dowel hole in sprocket and install sprocket on camshaft. *Do not attempt to drive sprocket on camshaft as welch plug at rear of engine can be dislodged.*
9. Draw sprocket onto camshaft, using the three mounting bolts. Tighten to 15-20 lb. ft. torque.
10. Lubricate timing chain and install cover.

V8-322 Engine

After removing the cover as outlined above, use two large screwdrivers to alternately work the camshaft and crankshaft sprockets outward until the camshaft sprocket is free of the camshaft. Remove this sprocket and chain and then remove the crankshaft sprocket.

Install the chain and sprockets as shown in Fig. 29.

Fig. 30 Using round-nosed punch to stake camshaft bearings in place. 1952-62 Six

CAMSHAFT

4-153, 6-230, 6-292 Engines

To remove the camshaft, remove radiator, grille, push rods, valve lifters, oil pan, vibration damper (6 cyl) or pulley (4 cyl), and timing case cover. Then pull out camshaft and gear assembly.

If necessary to replace bearings, the engine will have to be removed from the chassis. Then remove camshaft, flywheel and crankshaft. Drive out the expansion plug at the rear of the rear camshaft bearing and use suitable equipment to remove and replace the bearings.

1952-62 Six

Camshaft end play should be from .001" to .005" and is controlled by a thrust plate at the front end of the shaft. This clearance can be checked by inserting a feeler ribbon between the front end of the shaft and the thrust plate, Fig. 23.

If necessary to replace bearings, drive out the expansion plug at the rear of the rear bearing and use suitable equipment to remove and replace the bearings.

Service Note

Be sure the oil holes in the bearings are lined up with the oil holes in the crankcase. Before reaming the bearings, insert a round-nosed punch, Fig. 30, through the oil passage from the main to the camshaft bearings and stake each bearing in place.

V8-265, 283, 327, 348, 409

To remove the camshaft, remove valve lifters, fuel pump and its push rod, radiator, timing chain and camshaft sprocket. Install two 5/16"-18 x 4" bolts in two camshaft bolt holes. Using these bolts as a puller, remove camshaft from engine.

V8-322 Engine

The camshaft is supported in five steel-backed babbitt-lined bearings which are pressed into the block. The bearings must be line-reamed to size after being pressed into place. Since this operation requires special reaming equipment the original bearings should be retained unless severely damaged.

Slightly scored camshaft bearings will be satisfactory if the surface of the camshaft journals are polished and bearings are cleaned up to remove burrs, and the fit of the bearings is free.

Camshaft end play is controlled by a spacing ring located between the camshaft front bearing journal and a thrust plate attached to the block behind the camshaft sprocket. The spacing ring provides the necessary clearance or end play when the sprocket is tightened against it by the sprocket bolt.

Fig. 29 Valve timing. V8-322 engine

Important—When a new camshaft is installed, make certain that it is the correct part for the type of valve mechanism in the engine. Use of a camshaft designed for an engine with hydraulic valve lifters, or vice-versa, will result in extremely rough and noisy engine operation.

PISTONS & RODS, REMOVE

All Models

After removing the cylinder head as outlined previously, examine the cylinder bores above the ring travel area. If the bores are worn so that a shoulder or ridge exists at this point, remove the ridge with a ridge reamer to avoid damaging rings or cracking ring lands of pistons during removal.

Remove the connecting rod caps and push the pistons and rods out of the cylinders, using care to prevent rod bolts from contacting and nicking crankshaft journals.

Make sure the rods and pistons are properly numbered so they can be installed in the original locations. It is advisable to install caps on rods to avoid mixing parts.

PISTON & ROD, ASSEMBLE

4-153, 6-230, 6-292 Engines

Position the connecting rod in its respective piston so that the flange or heavy side of the rod at the bearing end will be toward the front of the piston (cast depression in top of piston head). Of course, when installed in the cylinder, the cast impression in the piston head will face the front of the engine.

Fig. 31 Correct assembly of pistons and rods. V8-265, 283, 327, 348, 409

1952-62 Six

The connecting rod should be assembled to the piston so that when placed in the cylinder bore, the piston pin clamp bolt faces the camshaft side of the engine.

V8-265, 283, 327, 348, 409

All pistons have an "F" cast on the front side. There is also a notch cast in the top of the piston head at the front to facilitate proper installation, Fig. 31. The piston assemblies should always be installed with the notch toward the front of the engine.

The odd numbered piston assemblies will always be installed in the left bank of cylinders, while the even numbered piston assemblies will always be installed in the right bank of cylinders.

One side of the connecting rod will have two machined bosses. This side of the rod and cap of the two adjacent rods on each crankpin will always be facing each other. This means that the machined bosses on odd numbered rods will always be facing the front of the engine, while the machined bosses on even numbered rods will be facing the rear of the engine.

V8-322 Engine

The piston and rod should be assembled so that the valve depressions in the piston head are on the camshaft side. And when installed in the engine the valve depressions in the piston head will be toward the inner side of the cylinder block, Fig. 32.

PISTONS

A .001″ oversize piston is available for service use so that proper clearances can be obtained for slightly worn cylinder bores requiring only light honing to clean up the bores. In addition, oversizes of .020″, .030″ and .040″ are available. If the cylinders have less than .005″ taper or wear they can be reconditioned with a hone and fitted with the .001″ oversize piston.

PISTON PINS

4-153, 6-230, 6-292 Engines

Piston pins are a matched fit to the piston and are not available from Chevrolet separately. Piston pins will not become loose enough to cause a knock or tapping until after very high mileage. In such cases, a new piston and pin assembly should be installed.

Piston pins should be capable of supporting their own weight in either pin boss when coated with light engine oil and at 60°F. Higher or lower temperatures will cause false indications.

V8 Engines

Piston pins are mounted off center and are a tight press fit in the connecting rods and pivot in the pistons. Pins should be capable of supporting their own weight in either pin boss when coated with light engine oil at 60°F. temperature. Higher or lower temperatures will cause false indications. Pistons and pins are supplied as an assembly.

1954-62 Chevrolet 6

Pistons used in these engines are aluminum and not fitted with bushings.

To remove a piston pin, remove the piston pin clamp bolt and expand the clamp slot with a screwdriver or other suitable means. Then push the pin out of the piston with hand pressure. If it cannot be removed with hand pressure, use a suitable drift to drive it out.

When removing a pin with a drift, hold the piston in one hand, insert the drift and tap lightly with a hammer. Do not hold the connecting rod during this operation, otherwise misalignment of the rod may occur.

If the new pin cannot be installed in the piston with thumb pressure, enlarge the holes with an expansion reamer. Take only a light cut with the reamer. Ream the holes until the pin can be pushed into the piston with the pressure of both thumbs.

PISTON RINGS, REPLACE

All Models

When new piston rings are installed without reboring cylinders, the glazed cylinder walls should be slightly dulled, but without increasing the bore diameter. This is done with a "Glazebuster" or with a hone equipped with the finest grade of stones.

New piston rings must be checked for clearance in piston grooves and for gap in cylinder bores. Cylinder bores and piston grooves must be clean, dry and free of carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring, Fig. 33. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and a false measurement of clearance will result.

Fig. 32 Correct assembly of pistons and rods. V8-322 engine

If the piston grooves have worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of new rings and the ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

ROD BEARINGS

Connecting rod bearing inserts are available in standard size and undersizes of .002″, .010″, .020″ and .030″. The bearings can be replaced without removing the rod assembly by removing the cap and replacing the upper and lower halves of the bearing. The clearance between the bearing and crankshaft can be measured by the use of Plastigage as follows:

1. Remove bearing cap and wipe oil from crankshaft journal and bearing insert.
2. With crankpin at approximately bottom dead center, place a piece of Plastigage in the center of the cap.
3. Reinstall the cap and tighten to the torque value given in the *Engine Tightening* chart.

Fig. 33 Checking ring clearance in groove

Fig. 34 Checking bearing clearance with Plastigage

4. Remove bearing cap and determine bearing clearance by comparing the width of the flattened Plastigage at its widest point with the graduation on the Plastigage scale, Fig. 34. The number within the graduation on the envelope indicates the clearance in thousands of an inch. If this clearance is greater than .004″ on an old bearing or greater than .003″ on a new bearing, or less than .001″, replace the bearing.

MAIN BEARINGS

4-153, 6-230, 6-292 Engines

Service Note

The rear main bearing journal has no oil hole drilling. To remove the upper bearing half (bearing half with oil hole) proceed as follows after cap is removed:

1. Use a small drift punch and hammer to start the bearing rotating out of the block.
2. Use a pair of pliers (tape jaws) to hold the bearing thrust surface to the oil slinger and rotate the crankshaft to pull the bearing out.
3. To install, start the bearing (side not notched) into side of block by hand, then use pliers as before to turn bearing half into place.
4. The last ¼″ movement may be done by holding just the slinger with the pliers or tap in place with a drift punch.

Fig. 36 Crankshaft rear oil seal. 4-153, 6-230, 6-292 engines

1952-55 Six

1. Remove radiator, vibration damper, fan belt, and spark plugs.
2. Loosen all rocker arm screws to relieve tension on camshaft.
3. Raise front and rear of vehicle about 8″ off floor, keeping it level.
4. Remove transmission floor pan and flywheel underpan.
5. Unfasten transmission support from cross member.
6. Uncouple gearshift selector rod from selector lever.
7. Raise rear of engine and support it with a bar across frame braces.
8. Release clutch fork from ball.
9. Unfasten transmission and slide it back about ¾″.
10. Remove oil pan and timing gear cover.
11. Remove oil pump and screen.
12. Rotate crankshaft to best possible position for removal of all bearing caps and mark timing gear position to allow for reassembly in same position.
13. Loosen all main bearing cap bolts, allowing crankshaft to drop about ⅜″.
14. Remove No. 2 and 4 bearing caps and take out upper and lower shells.
15. Install new upper bearing shells, locating dowel in hole and pressing bearings in place. If bearing has correct spread, shells should snap into place.

Bearings, Adjust

16. Install new lower bearing shells and replace caps, using three .002″ shims on each side of bearing. Draw bolts up until cap is snug to crankshaft, but not so tight as to raise crankshaft.
17. Repeat steps 14, 15 and 16 for No. 1 and 3 bearings.
18. Place jack under No. 3 bearing cap to raise crankshaft, keeping shaft horizontal and making sure all upper bearings remain in place. Also see that crankshaft gear meshes with camshaft gear at previously marked tooth position.
19. Draw all bearing caps up snug, then remove jack.
20. Starting with the rear bearing, remove shims evenly until there is a slight drag on crankshaft (when turned by hand) with bolts pulled up snug. Then replace a .002″ shim on one side. Again tighten bolts. The shaft should now turn freely. Loosen bolts of this bearing and follow same procedure with other bearings. Shims should be removed evenly, if possible. When they are not even, have the greatest number of shims on the same side of all bearings.
21. Complete the job by replacing the parts that were removed.

All V8 & 1956-62 Six

Shell type bearings are used, and if worn more than .004″ should be replaced. No attempt should be made to shim, file or otherwise take up worn bearings. To install new bearings:

1. Remove oil pan and spark plugs.
2. Remove cap and take out worn lower shell.

Fig. 35 Tool for removing upper main bearing shells. All V8's and 1956-62 Six cylinder engines

3. Rotate the crankshaft in the normal direction to turn the upper shell out of the crankcase, using a flattened cotter pin in the oil hole in the crankshaft to contact the shell and force it out, Fig. 35.
4. Place the new upper shell on the crankshaft journal with the locating notch in the correct position and rotate the shaft to turn the shell in place.
5. Install the lower shell in the cap and install the cap.
6. Bearing clearance can best be measured with Plastigage as outlined for the rod bearings. However, when one main bearing is being checked, the other four caps should be tight unless the engine is out of the chassis and upside down.
7. The bearing caps are marked with an arrow for identification purposes. The caps should be installed with the arrows pointing toward the front of the engine.

Fig. 37 Rolling oil seal in rear main bearing cap. 1952-62 Six and 1955-58 V8's

CRANKSHAFT REAR OIL SEAL

4-153, 6-230, 6-292 Engines

Both halves of the seal, Fig. 36 can be removed without removal of the crankshaft. Always replace upper and lower seal as a unit.

1. Remove oil pan and rear main bearing cap.
2. Remove seal from groove, prying from bottom with a small screwdriver.
3. Clean crankshaft surface. Then insert a new seal, well lubricated with engine oil, in bearing cap groove. *Keep oil off parting line surface as this surface is treated with glue....*
4. Gradually push with a hammer handle until seal is rolled into place.
5. To replace upper half of seal, use a small hammer and brass pin punch to tap one end of seal until it protrudes far enough to be removed with pliers. Install the new seal.
6. Install bearing cap and oil pan.

1952-62 Six & 1955-58 V8's

The rear bearing cap and crankcase have a groove into which a wick-type seal is rolled, Fig. 37. As it would be necessary to remove the engine and crankshaft to install the wick seal in the crankcase, this seal should always be renewed when new bearings are installed.

To install a new seal in the rear main bearing cap, insert the seal in the groove with the fingers. Then using a rounded tool, roll the seal down into the groove. Start at one end and roll to the center. Start again at the other end and roll to the center. The small portion of the seal which protrudes from the groove at each end should be cut off flush with a sharp knife. To prevent pulling the seal out of the groove, use a round block of wood the same diameter as the crankshaft to hold the seal firmly while cutting it off.

1959-63 V8 Rubber Seal

A neoprene seal is used in the rear main bearing cap in these engines. To change the seal (engine in vehicle) proceed as follows:

1. Remove rear bearing cap.
2. Remove oil seal from groove, prying from bottom, using a small screwdriver.
3. Clean crankshaft surface.
4. Install new seal well lubricated on lip only with engine oil and, with lip facing front of engine, with finger and thumb, roll seal in place. *Keep oil off parting line surface of seal as this is treated with glue.*
5. To replace upper half of seal, use a small hammer and tap a brass pin punch to one end of seal until it protrudes far enough to be removed with pliers.
6. Be careful of seal retainer tang while inserting a new seal so that it doesn't cut the seal.
7. Insert a new seal well lubricated with engine oil in groove. Gradually push with hammer handle until seal is rolled into place. *Keep oil off parting line surface as this surface is treated with glue.* Install bearing cap.

OIL PAN, REPLACE

1963 Four & Six Cylinder Except 292 In 10-30 Series Trucks

1. Raise front of vehicle and place on stand jacks.
2. Drain Engine oil.
3. On Powerglide only, remove starter.
4. Unfasten and remove oil pan.

6-292 In 10-30 Series Trucks

1. Raise front of vehicle and place on stand jacks.
2. Drain engine oil.
3. On powerglide only, remove starter.
4. Remove engine front mount-to-frame bracket bolt (both sides).
5. Remove radiator and shroud.
6. Raise engine enough to place a short piece of 2 x 4 between mount and frame bracket.
7. Unfasten and remove oil pan.

1952-62 Six

On Sedan Delivery models with independent front suspension, unfasten the steering idler and third arm from the frame front cross member and let the assembly drop down. Carefully note the number of shims used between the upper mounting bolt and cross member so that the same number may be installed when replacing the assembly.

On all models, the pan is removed by simply unfastening it from the block and lowering it to the floor.

V8 Engines

1. Drain the oil. On Taskmaster and Workmaster engines, remove oil level gauge, tube and seal from oil pan. Remove retaining bolts and screws and remove oil pan.
2. Clean all gasket surfaces.
3. Install rear oil pan seal in groove in rear main bearing cap. Tuck ends into groove openings in cylinder block.
4. Install side gaskets on pan rails, using grease as a retainer. Rear end of side gaskets lap rear end gasket. Tuck front ends of side gaskets into gap between front end cover seal groove and cylinder block.
5. Install oil pan front seal in groove in front end cover, with ends butting side gaskets.
6. Install oil pan and bolts.

OIL PUMP

4-153, 6-230, 6-292 Engines

The pumps used in these engines are of the positive gear type. After disassembling the pump, examine the shaft and gears for excessive wear and replace where necessary, or better still, install a new pump. When assembling the pump, be sure the ground side of the idler gear is toward the cover.

The gasket used between the pump cover and the body is special in that it controls the clearance in the pump. If the relief valve parts show wear, install new parts. Be sure that the tapered set screw which holds the pump in place is fully seated and locked with its lock nut.

1952-62 Six

The pumps used in these engines are of the positive gear type. After disassembling the pump, examine the shaft and gears for excessive wear and replace where necessary, or better still, install a new pump. When assembling the pump, be sure the ground side of the idler gear is toward the cover.

Service Note

The gasket which is used between the pump cover and the body is special in that it controls the clearance in the pump. If the relief valve parts show wear, install new parts. Be sure that the tapered set screw which holds the pump in place is fully seated and locked with its lock nut.

V8 Engines

The oil pump consists of two gears and a pressure relief valve enclosed in a two-piece housing. Inasmuch as the pump is serviced on an exchange basis no repair operations other than disassembly, cleaning and inspection are covered here.

After removing the oil pan, unfasten pump from rear main bearing cap. Disconnect pump shaft from extension by removing clip from collar. Remove pump cover and take out idler gear, drive gear and shaft.

Should any of the following conditions be found it is advisable to replace the pump assembly.

1. Inspect pump body for cracks or wear.
2. Inspect gears for wear or damage.
3. Check shaft for looseness in housing.
4. Check inside of cover for wear that would permit oil to leak past the ends of gear.
5. Check oil pick-up screen for damage to screen, by-pass valve or body.
6. Check for oil in air chamber.

Assembly

1. Place drive gear and shaft in body.
2. Install idler gear so its smooth side is toward cover.
3. Install cover and tighten screws to 6-9 lb. ft. and check to see that shaft turns freely.
4. Install pick-up screen on pipe and bend float travel control tang back in place.
5. Assemble collar end of extension shaft over pump drive shaft, aligning tang of extension shaft with slot in end of pump drive shaft. Install retaining clip with flat end in groove of drive shaft.
6. Assemble pump and extension shaft to rear main bearing cap, aligning slot on top end of extension shaft with drive tang on lower end of distributor drive shaft.
7. Install pump to rear main bearing cap bolt and tighten to 45-50 lb. ft.
8. Install oil pan.

Fig. 38 Water pump. V8-265, 283, 327, 348, 409

WATER PUMP

4-153, 6-230, 6-292 Engines

1. After unfastening the pump, pull it straight out of the cylinder block to avoid damage to the impeller and shaft.
2. When disassembling the pump, support the fan hub in an arbor press and press pump shaft out of hub. A ½" x 2" bar will allow the shaft to be pushed through the hub.
3. Support pump in arbor press and press shaft and impeller out of pump, applying pressure on outer race of bearing only. *Shaft and bearing must not be pushed out of housing by applying force on shaft or bearings will be damaged. Use a ⅞" deep socket or piece of tubing 1⅛" O.D.* Shaft and bearing should be pressed out of rear of pump body only.
4. Support impeller on seal surface. Using a ½" x 2" pin, press shaft out of impeller. Discard seal.
5. When assembling pump, apply pressure to outer race of shaft bearing until it is flush with front of pump body.
6. Lightly coat O.D. of new seal with sealing compound and press into place, applying pressure to seal outer flange. Seal should bottom with outer flange against pump body.
7. Press on fan hub, being sure it is positioned so that fan belt operation will not be hampered.

1955-62 Six

The pump used on these models is similar to that used on V8 engines except that the V8 pump has a back plate. Therefore, follow the procedure outlined for the V8 pump.

To remove the pump, drain radiator and remove water inlet hose from pump. Remove fan belt. On heater-equipped models, remove hose from pump housing. Unfasten pump from engine and pull pump straight out of cylinder block to prevent damage to impeller and shaft.

Install the pump in the reverse order of removal and adjust the fan belt.

V8-265, 283, 327, 348, 409

1. Drain radiator and remove water inlet hose from pump.
2. Remove fan belt.
3. On heater equipped models, remove hose from pump housing.
4. Unfasten pump from engine and lift off.
5. Remove fan and pulley, Fig. 38.
6. Remove pump back plate.
7. Support fan hub on arbor press and press pump shaft out of hub.
8. Support pump on cylinder block face and press shaft and impeller out of pump, applying pressure on outer race of shaft bearing only. Shaft and bearing assembly must not be pushed out of housing by applying force on shaft or bearings will be damaged. Use a ⅞" deep socket or a piece of tubing 1⅛" O. D.
9. Press shaft out of impeller. Discard seal.

Assembly & Installation

Inspect all parts for wear or damage. Do not submerge shaft bearing in cleaning solvent as it is permanently sealed and lubricated.

Assemble pump in reverse order of disassembly. When installing the seal see that it bottoms with the outer flange against the pump body. The impeller should be pressed on the shaft so that there is .010" to .035" clearance between impeller vanes and pump body. See Fig. 45 for position of shaft, fan hub and impeller in pump housing.

V8-322 Engine

To remove and repair the water pump on these models, refer to Fig. 39 and proceed as follows:

1. Drain cooling system.
2. Loosen fan belt and remove fan blades, spacer and puller from hub on water pump shaft.
3. Remove fan belt.
4. Disconnect hose from water pump inlet and remove pump cover and gasket from timing chain cover.
5. Remove impeller from pump shaft, using a puller with two hooks if available. If not, a three-hook puller may be used.
6. Remove carbon washer, rubber bellows and spring from brass sleeve that is pressed into pump housing. It is not necessary to remove the brass sleeve if it is in good condition. If sleeve is doubtful, however, remove by driving it out with a punch inserted through the vent hole in pump body.
7. Thoroughly clean pump cover to remove rust, old gasket, etc. Do not soak in cleaning solvent as this may leak into pump shaft bearing and destroy the lubricant.
8. Check pump shaft bearing for end play or roughness in operation. If the bearing is not in serviceable condition, press the fan hub off the shaft, remove the bearing retainer, then press the bearing out toward the *front* of the pump cover.

Fig. 39 Water pump. V8-322 engine

Assembly & Installation

1. If the old pump bearing was removed, press a new bearing in against the shoulder in the pump cover (long end first) and install the bearing retainer.
2. Use care to start the fan hub squarely on the front end of the shaft and press it into position $\frac{13}{64}$" from end of shaft.
3. If the old brass sleeve was removed, carefully press the sleeve of the new seal into place, using a thick walled tube of proper inside and outside diameters to bear fully against flange of sleeve. It is not necessary to remove the other seal parts from sleeve.
4. If the old sleeve was not removed, separate the new seal sleeve from seal bellows by soaking in hot water to soften the cement used to hold the seal parts together for ease of handling. Install carbon washer, bellows and spring assembly in the old sleeve in the pump body, being careful to engage the two notches in the washer with the driving dents in the brass sleeve.
5. Coat the face of the carbon washer and impeller hub with rust preventative or Seco oil. Then support the pump on the fan end of the shaft and press the impeller on the inner end of the shaft until the rear face of the impeller is flush with the end of the shaft.
6. Make sure gasket surfaces are clean. Then install pump cover with new gasket and tighten bolts uniformly.
7. Connect pump inlet hose, fill cooling system and check for leaks.
8. Install fan pulley, spacer, fan blade and belt.

RADIATOR, REPLACE

Conventional Models

After draining the radiator and removing attaching hoses, unfasten the radiator from its support and lift out. On models that use a shroud, the shroud may be pushed back and allowed to drop in back of the fan blades.

Fig. 40 Ignition details. 1955-56 V8-265

Fig. 41 Ignition details. 1957-62 V8-265, 283, 327

Cab-Over-Engine Models

Radiator removal on these models is accomplished in the same manner as on conventional models except that the hood and air cleaner must be removed.

Forward Control Models

1. Remove radiator grille.
2. Drain radiator.
3. Disconnect windshield wiper hose and the compartment light wire.
4. Disconnect horn wires at horn.
5. Remove horn and bracket.
6. Remove upper, lower and both side radiator baffles.
7. Remove radiator filler pipe hose and radiator overflow extension pipe hose.
8. Raise engine cover and prop open.
9. Disconnect radiator hoses.
10. Disconnect radiator support from frame cross member.
11. Disconnect radiator support from upper attaching brackets.
12. Remove radiator and its support.
13. Disconnect radiator from its support and remove.
14. Reverse the foregoing procedure to install.

Fig. 42 Ignition details. V8-348, 409

IGNITION TIMING

If a timing light is to be used to set ignition timing, disconnect the vacuum advance pipe to the carburetor and place a piece of tape over open end of pipe. *This is important as carburetor trouble can affect timing adjustments.*

Lacking a power timing light, an accurate method of setting ignition timing with the engine stopped is with the aid of a jumper light. Be sure to use a light bulb that corresponds with the system voltage of the vehicle.

1. Remove distributor cap and rotor and see that the breaker gap is set according to specifications.
2. Rotate engine until No. 1 cylinder is at the ignition timing point as indicated by the timing pointer and timing mark being lined up with each other.
3. Connect the jumper light between ignition terminal and ground.
4. Turn on ignition switch.
5. Loosen distributor and turn it in the direction of normal rotation until the points just close (light out). Then slowly turn distributor in the opposite direction just to the exact point that the light goes on. Tighten distributor in this position. See Figs. 40, 41, 42.

1963 Service Note for "P" Series

The 4-153 and 6-230 engines have the timing pointer located on the right side of the timing cover as viewed from the front of the engine. Due to the body configuration of the "P" Series trucks, it is very difficult and dangerous to check the ignition timing from above through the engine access cover. For these reasons an additional timing pointer is installed at the front of the oil pan on all engines used in "P" Series trucks.

Timing will be a two man operation with one man using the timing light under the vehicle and the other in the cab to rotate the distributor. *Both engines will be timed to the No. 2 cylinder, using the oil pan mounted pointer.*

Carburetor Section

Performance Complaints

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any iron oxide dust that may have caused intake needle and seat leakage.

Inspect gasketed surfaces between body and air horn. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to "cutting-out on turns" complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the floats and intake needle and seats may be checked under pressure if the fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge of the pump jets.

Poor Mileage and Engine Loading Complaints

Cases of poor mileage and engine loading on carburetors with automatic choke may be due in many instances to sluggish choke valve opening during cold driveaway, caused by insufficient vacuum in choke housing, a plugged or restricted heat pipe or inlet in choke cover. To check for this condition, have engine warm and running at slow idle. Remove choke heat pipe and hold a finger over the heat inlet hole (hole is on choke housing on some carburetors). If there is little or no vacuum pull on the finger, check the choke housing for gasket leaks or plugged vacuum passages. If these are all right, check choke vacuum passages in carburetor between choke housing and manifold.

Dirty or Rusty Automatic Choke Housing

In cases where it is found that the interior of the choke housing is dirty, gummed or rusty while the carburetor itself is comparatively clean, look for a punctured or eroded manifold heat tube (if one is used).

Idle Speed & Mixture Adjustments

The initial setting of the idle mixture screw (or screws) is listed in the carburetor charts. Turn the screw clockwise by hand until it just contacts its seat lightly. Then turn it out the number of turns listed. Start the engine and run it until it reaches normal operating temperature, at which time the choke valve should be wide open with the idle speed screw resting on the lowest step of the fast idle cam. Slowly turn the screw a little at a time until the engine shows a tendency to hesitate and stall. Then turn it to the left until the engine runs smoothly. Continue turning the screw to the left until the mixture is rich and the engine starts to "lope" or "gallop". Finally turn the screw to the right until the engine runs evenly.

On two-barrel carburetors, there is an idle mixture screw for each barrel. On four-barrel carburetors there are also two idle mixture screws on the primary side of the carburetor. When idle ports are provided on the secondary side, they are non-adjustable or they are rendered non-functional by being blocked with gaskets.

When adjusting the idle mixture on two and four-barrel carburetors, adjust one screw at a time until the engine runs smoothly as directed above. Then adjust the other screw in like manner.

After the idle mixture has been adjusted, it is recommended that a tachometer (engine speed indicator) be used to adjust the slow idle speed to the rpm listed in the *Tune Up Chart*. If a tachometer is not available, adjust the idle speed screw until the engine runs smoothly without racing. If the car has an automatic transmission, place the shift lever in Drive range with hand brake off. Then very slowly increase engine speed until the car begins to creep, then back off slightly until creeping is eliminated.

④—With bowl cover held upright, measure from free end of float to bowl cover. Adjust by bending stop tabs on float arm.

⑤—With throttle valve seated, press down on upper end of diaphragm shaft until it bottoms. Metering rod arm should now contact pump lifter link at outer end nearest springs. Adjust by bending pump connector link at lower angle.

⑥—With throttle valve seated, press down on upper end of diaphragm shaft until diaphragm bottoms in vacuum chamber. Metering rod should contact bottom of metering rod well and metering rod arm should contact lifter link at outer end nearest springs and at supporting lug. Adjust by bending lip of metering rod arm to which rod is attached.

⑦—With choke held wide open, lip on fast idle arm should contact boss on body casting. Adjust by bending offset portion of choke connector link.

⑧—With choke housing and baffle plate removed, crack throttle valve and hold choke valve closed; then close throttle. With choke valve held closed and slight tension on throttle lever, there should be the clearance listed between throttle valve and carburetor bore (side opposite idle port). Adjust by bending connector link at lower angle.

⑨—Hold throttle valve wide open and close choke valve as far as possible without forcing. There should be the clearance listed between lower edge of choke valve and inner wall of air horn. Adjust by bending arm of choke trip lever.

CARBURETOR GOVERNOR

Velocity Type

This governor, Fig. 1, is available on all truck models with the exception of the ¾ and 1 ton Forward Control. The governor is mounted between the carburetor and intake manifold and automatically governs the maximum speed at which the engine may be operated.

The gas mixture rushing from the carburetor through the governor throat strikes the offset throttle valve and tends to draw it closed. This action is opposed by a governor spring which is attached to the valve shaft through a cam ribbon and cam. By adjusting the pull of this spring, the governor valve may be made to remain open, and then closed at a predetermined engine speed. Adjustment of the spring pull is accomplished by changing number of coils operating.

Governor Adjustment

All governors are calibrated and adjusted in assembly to insure accurate control of the maximum engine speed of the model vehicle for which it is intended. However, there will be occasions when minor adjustments are required to satisfy local conditions.

To adjust a governor for higher speed, turn the adjusting cap counter-clockwise or to the left; for lower speeds turn the cap to the right or clockwise. One turn on the adjusting screw will change the speed 300-400 rpm or 4 and 5 mph.

When a more sensitive regulation is desired or if the governor is too sensitive and inclined to surge, correct the adjustment as follows by means of the calibrating nut shown at "A", Fig. 2.

If Governor is too Sensitive—If the governor is too sensitive or on the point of surging, remove the adjusting cap and hexagonal shaft assembly and place the special hollow wrench (A-24283) in position on nut "A". Insert the special adjusting wrench (A-25264) through this wrench and turn the main adjusting screw "B" to the right one turn. (These wrenches are available at King-Seeley Distributors.) With the hollow wrench in the slot of nut "A", turn this nut to the right about ¼ turn. The main adjusting screw "B" must be kept from turning while nut "A" is adjusted.

If Governor is Not Stable—If a more sensitive governor is desired, adjust main screw "B" to the left one turn and, while holding this screw in the new position, turn nut "A" to the left ¼ turn at a time until the desired regulation is obtained. When the adjustment is completed, tap lightly on the end of the hollow wrench so that nut "A" will seat properly.

Vacuum Spinner Type

This type governor, Fig. 3, is a mechanically-driven vacuum-actuated mechanism set to govern engine speed at 4000 rpm maximum under full load

Fig. 2 Governor adjustment. Six-cyl.

Fig. 1 Cutaway view of carburetor governor. Six-cylinder

conditions. The governor is comprised of two basic units: the centrifugal control valve housed in the distributor and a carburetor actuator which is mounted on the carburetor throttle body. These two components are inter-connected by tubing.

The throttle lever is connected to the throttle shaft in such a manner that turning the throttle lever does not actually force the throttle valves open but rather allows them to follow the throttle lever because of the governor spring tension. Thus when the throttle lever is moved to wide open position, the position of the throttle valve will be determined by vacuum on the diaphragm and the tension of the governor or spring acting on the governor lever.

Vacuum and free operation are two keys to correct operation of the Rochester governor. If all the parts are free to move as intended, and there are no vacuum leaks, the unit will operate correctly.

Governor Adjustment

Since governing speed is a function of both the distributor "spinner" and the carburetor actuator, the only positive method of accurately setting speed is to adjust the spinner on the vehicle. For extremely accurate full throttle governing, road testing is necessary. However, for practical purposes, it can be assumed full throttle governed speed will be about 200 rpm below no load governed speed, and adjustment can be made by "revving" the engine against the governor with the vehicle in neutral.

To increase governing speed turn the nut on the spinner shaft (in distributor) clockwise, Fig. 3. To lower governing speed turn nut counterclockwise.

If the governing system is to operate satisfactorily for long periods, the vacuum passages must be kept free from dirt. To insure this, the carburetor air cleaner should be cleaned often enough to prevent its saturation with dirt to the extent that the governing system cannot obtain its supply of clean air. The cover bands or plugs, whichever are used to seal the "spinner" compartment should always be properly and tightly in place whenever the vehicle is in operation. Since a slight partial vacuum always exists in this compartment, dirt could be pulled into the spinner unit if air leakage is permitted.

Fig. 3 Vacuum spinner type governor. Rochester 2G carburetor; typical of 4G

Clutch Section

HYDRAULIC CONTROLS

1960-63

Hydraulic operated clutch controls are used on all models except Forward Control to release both the Coil Spring Clutch and the Diaphragm Spring Clutch. Fig. 1 shows a dual master cylinder, one side for clutch operation and the other for brake. A single clutch master cylinder is used in conjunction with air brakes.

When the clutch pedal is depressed, brake fluid is forced from the master cylinder, Fig. 1, into the slave cylinder, Fig. 2, and the slave cylinder push rod moves the clutch release lever. When the clutch pedal is released, fluid from the slave cylinder feeds back to the master cylinder.

A "bleeder" fitting is provided on the slave cylinder and the procedure for bleeding the system is similar to that used on the brake system. Fluid level in the master cylinder should be maintained ½" below the top of the cylinder.

Clutch Pedal, Adjust

Two adjustments are necessary: pedal total travel, and pedal free travel. The

Fig. 1 Dual master cylinder for clutch and brake operation. 1960-63

Fig. 2 Slave cylinder and clutch fork. Be sure to note which fulcrum is used ("A" or "B") before disassembly

Fig. 3 Clutch pedal bumper. 1960-62

Fig. 4 Adjusting slave cylinder push rod. 1960-63

master cylinder must be filled to ½" below the top of the reservoir and the system must be free of air.

Clutch Pedal Total Travel

1. On 1960-62, loosen clutch pedal bumper, Fig. 3, so clutch pedal pad, in the fully released position, is even with the brake pedal pad (except on 1961 Series 60 through 80 in which brake pedal is ⅝" higher).
2. On all models disconnect clutch fork return spring.
3. Bottom the slave cylinder push rod and piston by pushing the slave cylinder push rod to the front of the vehicle as far as it will go, Fig. 4.
4. Pull clutch fork toward rear of vehicle until the throwout bearing touches the pressure plate release levers.
5. Adjust clearance between slave cylinder push rod fulcrum ("V" block), Fig. 2, by adjusting the nut behind it to $\frac{5}{32}$" clearance between fulcrum pivot and clutch fork, Fig. 4. This clearance can be checked with the shank of a $\frac{5}{32}$" drill.

Clutch Pedal Free Travel 1960-62

Adjust clutch master cylinder push rod eccentric bolt on early models and adjustable push rod on late models to obtain free travel between the clutch master cylinder push rod and the master cylinder piston, Fig. 5. This will insure the master cylinder piston moving sufficiently to uncover the port in the master cylinder reservoir.

1963

Adjust clutch master cylinder adjustable push rod to obtain free travel between push rod and master cylinder piston. This will amount to ⅛" free pedal travel measured at the center line of the clutch pedal pad just before the clutch push rod touches the master cylinder piston.

Adjust 1961 Tilt Cab Over-Center Linkage

1. Disconnect over-center push rod extension from over-center lever.
2. Adjust clutch slave cylinder push rod to clutch fork clearance as outlined above for conventional models.
3. With over-center spring installed and over-center lever against stop, adjust over-center push rod extension clevis so rod end freely enters hole in over-center lever. Secure adjustment.

CLUTCH PEDAL, ADJUST

1955-62 Mechanical Linkage

Free travel of the clutch pedal should be maintained at from ¾" to 1". To adjust, loosen the lock nut, Fig. 6, and turn the adjusting nut until the proper free pedal travel is obtained.

Check the free pedal travel with one finger on the pedal and not with the foot as the adjustment is sensitive.

Fig. 5 Adjusting clutch push rod (eccentric method). 1960-62

Fig. 6 Clutch pedal free travel adjustment. 1955-62 with mechanical linkage

Fig. 7 Clutch pedal free travel adjustment. 1963 with mechanical linkage

1963 Mechanical Linkage

1. Disconnect clutch fork return spring at fork.
2. Loosen nut "A", Fig. 7, and back off from swivel about ½".
3. Hold clutch fork push rod against fork to move clutch release bearing against clutch fingers (push rod will slide through swivel at cross-shaft).
4. Adjust nut "B" to obtain $\frac{3}{16}$ to ¼" clearance between nut "B" and swivel.
5. Release push rod, connect return spring and tighten nut "A" to lock swivel against nut "B".
6. Check free pedal travel which should be ¾ to 1".

CLUTCH SERVICE

1. Remove transmission as outlined further on.
2. On models with hydraulic clutch control disconnect slave cylinder from clutch fork.
3. Remove clutch throwout bearing from fork.
4. Remove clutch fork by pressing it away from its ball mounting with a screwdriver until the fork snaps loose from the ball.
5. Support clutch assembly during removal with a suitable pilot tool.
6. Loosen clutch attaching bolts one turn at a time to prevent distortion of clutch cover until diaphragm spring is released.
7. Remove clutch pilot tool and clutch from vehicle.

Manual Shift Transmission Section

For Clark, Fuller, New Process, Spicer and Warner transmissions used on Chevrolet trucks, see the "name" chapter for service procedures and lubricant capacities

Chevrolet Trans. Index & Lube Capacities

Trans. Type	Oil, Pints
3 Speed	2
4 Speed	6¼
Power Divider and Auxiliary Trans.	①

①—Fill to bottom of filler plug hole

CHEVROLET 3 SPEED, 1955-63

Remove & Replace

1. Disconnect speedometer cable, and the shift control rods from the levers at the transmission.
2. Split the rear universal joint and remove the propeller shaft and front universal joint.
3. Remove the two top transmission-to-clutch attaching bolts and insert guide studs in their place.
4. Remove the two lower attaching bolts and slide the transmission straight back on the guide studs until the clutch gear is free of the splines in the clutch disc.
5. Remove the transmission from under the chassis.
6. Reverse the above procedure to install the transmission, using the guide studs to prevent the weight of the transmission from hanging on the clutch disc.

Disassemble

1. Remove side cover and gasket, Fig. 1.
2. Remove main drive gear bearing retainer and remove the main drive gear and bearing.
3. Remove 24 roller rear pilot bearings, 2 washers and 14 roller front bearings.
4. Unfasten extension housing from transmission case and pull extension and mainshaft out of transmission case, leaving the synchronizer and first and reverse gear in case.
5. Remove synchronizer clutch sleeve and first and reverse gear through side opening in case.
6. Remove countershaft by driving it from front to rear of case, using a soft steel drift. Remove the countergear rollers and thrust washers.
7. Remove the countergear.
8. Drive the idler shaft lock pin into the shaft. This pin is shorter than the diameter of the shaft so the shaft may be slipped out when the pin is driven in.
9. Using a drift pin, tap rear of idler shaft to drive out plug ahead of shaft. Do not turn the shaft while removing as the lock pin may drop down between the idler gear bushings.
10. Remove reverse idler gear and thrust washers.
11. To remove the mainshaft from the extension, expand the bearing snap ring and tap the rear of the shaft with a soft hammer to bring the shaft, speedometer drive gear, second speed gear and bearing out of the extension as an assembly.

Fig. 1 Exploded view of 1955-63 standard three speed transmission

Mainshaft, Disassemble

1. Press speedometer gear off mainshaft, using suitable split plates in an arbor press.
2. Remove bearing-to-mainshaft snap ring and press bearing off shaft.
3. Remove second speed gear thrust washer, pull drive pin out of shaft and remove second speed gear.

Mainshaft, Assemble

1. Slide second speed gear on mainshaft, insert drive pin in shaft and install thrust washer against gear.
2. Install new bearing with groove in outside diameter of bearing toward second speed gear.
3. Select one of four available snap rings so end play of bearing on shaft is a maximum of .004". This may be determined by installing succes-

sively larger rings. Use the thickest ring that will enter snap ring groove on shaft.

4. Start speedometer drive gear on shaft with chamfered inside diameter of gear toward bearing. Press gear on shaft until forward face of gear is 7/8" from rear face of bearing.

CHEVROLET 4 SPEED

Remove & Replace

1. Remove screws which fasten steering jacket grommet to floor and slide grommet up on jacket out of the way.
2. Remove accelerator pedal and floor mat.
3. Remove sheet metal screws attaching transmission cover to body floor and remove cover. On Forward Control models, remove front and rear floor pans.
4. Remove speedometer cable from transmission rear bearing retainer.
5. On 1 ton models, remove cotter key and pin attaching parking brake pull rod assembly to parking lever.
6. On 1½ and 2 ton, disconnect parking brake lever return spring from parking brake operating lever and remove cotter key and pin attaching inner and outer levers to parking brake operating lever.
7. Remove parking brake lever lock, flat washer and spring and remove parking brake lever.
8. Drain lubricant from transmission.
9. On 1 ton models, break universal joint at transmission universal joint flange and tape bearings in the trunnions.
10. On 1½ and 2 ton models, disconnect intermediate universal joint by removing the two trunnion bearing U-clamps, split the joint and lower front end of rear propeller shaft to floor. Remove four universal flange nuts. Remove nuts attaching propeller shaft bearing support bracket to frame cross member and remove front propeller shaft and bearing assembly.
11. Remove two upper capscrews attaching transmission to clutch housing and install guide pins in these holes.
12. Remove flywheel underpan and remove two lower transmission-to-clutch housing bolts.
13. Slide the transmission straight back on the guide pins until the clutch gear is free of the splines of the clutch disc.
14. Remove transmission from vehicle.
15. Reverse the foregoing procedure to install the transmission, being sure to use the guide pins to prevent the transmission from hanging on the clutch disc.

Disassemble

1. Refer to Fig. 2 and remove transmission cover.
2. Remove reverse shifter lever bolt nut, screw bolt out of case and remove reverse shifter lever, spacer and flat washer.
3. Remove clutch gear bearing retainer and gasket and, with a puller, pull clutch gear from case. *Index cut-out section of clutch gear with countershaft driven gear to obtain clearance in removing clutch gear and shaft.*
4. Remove clutch gear synchronizer cone and transmission mainshaft pilot bearing roller spacer from end of mainshaft.
5. Remove speedometer driven gear from rear bearing retainer.
6. Place transmission in two gears at once to lock gears and remove universal joint flange retaining screw, lockwasher, plain washer and universal joint front flange.
7. Remove rear bearing retainer and gasket.
8. To remove mainshaft assembly the entire assembly must be pulled back to remove rear mainshaft bearing from case. Use a suitable puller (tool No. J-2667) to pull shaft and bearing out of case.
9. Remove puller from case and then move mainshaft back as far as it will go.
10. Use suitable puller (tool J-1619) to remove rear bearing from mainshaft.
11. With first and second speed sliding gear forward, raise front end up and lift shaft out of case.
12. To remove reverse idler gear, drive out shaft retaining pin, using a small punch. This pin is driven into the shaft, after which the shaft may be driven out of the case from front to rear. With shaft removed, take reverse idler gear from case.
13. To remove countershaft assembly, drive a punch through the countershaft front bearing spacer and pry out spacer.
14. Drive countershaft to the rear of the case, using a brass drift on the front end of the shaft, until rear bearing is driven out of case.
15. Remove rear bearing retainer bolt lock plate, retainer bolts and retainer.
16. Using a suitable bearing puller, remove rear bearing and oil deflector from rear end of countershaft.
17. Raise front end of countershaft and lift assembly from case.
18. Remove transmission chip collector from bottom of transmission case.

Clutch Gear

Remove mainshaft pilot bearing rollers from clutch gear and take roller retainer from recess in shaft. Place clutch shaft in a vise and, with a suitable spanner wrench (tool J-2670), remove bearing retaining nut, oil slinger and oil deflector. Use an arbor press to press gear and shaft out of bearing.

To assemble, press bearing on shaft. Then install oil deflector, oil slinger and retaining nut, noting that nut is designed to fit contour of oil slinger. When installing foregoing parts, make sure oil deflector centers around retainer nut hub. Place clutch shaft in vise and tighten retainer nut securely and stake in place. Apply a small amount of grease to bearing surfaces in shaft recess. Install 18 pilot bearing rollers and roller retainer. This retainer holds bearings in position and when transmission is assembled it is pushed forward into recess by mainshaft pilot.

Mainshaft, Disassemble

1. Remove clutch hub retainer ring from pilot end of mainshaft.
2. Support assembly on sliding gear in arbor press and press mainshaft out of gear cluster.
3. Remove clutch key springs from third and fourth speed clutch hub and remove sleeve from hub, being sure to account for three clutch keys.
4. Remove synchronizer cone from third speed gear.
5. Remove bushing from third speed gear and remove gear. *Second speed thrust washer goes between third and second speed gears.*
6. Remove second speed gear from synchronizer ring lugs.
7. Remove synchronizer ring retainer and synchronizer ring from first speed gear.

Mainshaft, Inspect

After washing all parts, proceed as follows:

1. Inspect mainshaft for scoring or excessive wear at thrust surfaces or splines.
2. Inspect clutch hub and sleeve for excessive wear and make sure sleeve slides freely on clutch hub. Also check fit of clutch hub on mainshaft splines. The third and fourth speed clutch sleeve should slide freely on the clutch hub but the clutch hub should be a snug fit on the mainshaft splines.
3. Inspect third speed gear thrust surfaces for excessive scoring and third speed gear bushing for excessive wear. The third speed gear must be a running fit on the mainshaft bushing and the bushing should be a press fit on the shaft.
4. Check second speed thrust washer for excessive scoring.
5. Inspect second speed gear for excessive wear at the thrust face or in the bronze bushing. Check synchronizer springs for looseness or breakage. Synchronizer springs may be replaced by removing the rivets and installing a new spring with new special rivets. If bushing is worn excessively, the gear assembly must be replaced.
6. Inspect second speed gear synchronizing ring for excessive wear.
7. Inspect bronze synchronizer cone in first speed gear for excessive wear or damage. Also inspect clutch gear synchronizer cone and third speed gear synchronizer cone for excessive wear or damage.
8. First speed sliding gear must be a sliding fit on mainshaft splines.
9. Inspect all gear teeth for excessive wear.

Mainshaft, Assemble

1. Install second speed gear synchronizing ring into first speed gear and install synchronizing ring retainer. Make sure ring retainer is seated fully in snap ring groove of first speed gear, Figs. 3 and 4.

64. Countershaft front roller bearing
65. Countershaft assembly
66. Countershaft rear bearing oil deflector
67. Countershaft rear bearing
68. Countershaft rear bearing retainer
69. Lock plate

2. Install first speed sliding gear on mainshaft splines with synchronizing ring toward front of shaft.
3. Install second speed gear on shaft with synchronizer springs toward synchronizing ring in first speed gear. Position gear so two cut-out sections index with prongs on synchronizing ring.
4. Install second speed gear thrust washer.
5. Install third speed gear bushing on mainshaft until it bottoms on second gear thrust washer.
6. Check second speed gear end play which should be .009″ to .015″.
7. Install third speed gear over mainshaft bushing and place synchronizing cone on taper of third speed gear.
8. Install clutch sleeve over clutch hub with taper toward long shoulder on hub and drop the three clutch keys into position. Install clutch key springs, one on each side of clutch hub, making sure springs fit under the clutch keys to hold them out.

Fig. 3 Detail of 3rd and 4th speed synchronizer. 1952-61 four speed transmission. For 1962-63 a spline lock feature is used for the 3rd and 4th gear clutch assembly

against clutch sleeve. Both springs must be installed in the same relative position to provide even tension on the clutch keys.

9. Support mainshaft assembly in an arbor press. Install clutch hub assembly with taper on clutch sleeve and long shoulder of clutch hub toward pilot on mainshaft. Then press clutch hub onto shaft until it bottoms. Make certain that slots in third speed gear synchronizing cone index with the three clutch keys in the clutch hub.
10. Check third speed gear end play which should be .010″ to .014″.
11. Install clutch hub retainer ring. The retainer ring is a selective lock ring and should be checked carefully for proper thickness at assembly. There are four thickness rings available.

Countershaft Gears, Replace

Should it be necessary to replace any of the countershaft gears, the lock ring on the front end of the shaft should first be removed and then the assembly supported on an arbor press and the shaft pressed out of the train of gears.

When reassembling the new gears to the countershaft, the radius end of the second speed gear faces the first speed gear. The third speed gear is installed next and inasmuch as both sides of this gear are identical it may be installed either way. The reverse speed gear is installed onto the shaft next so that the chamfered end of the teeth face the counter driven gear. Only one spacer is used and that is installed between the reverse gear and counter driven gear. The counter driven gear is installed last.

When pressing the gears on the countershaft, new drive pins should be used and, after all gears are pressed into position, the round pins should be driven $\frac{1}{32}$″ below flush with shoulder on counter driven gear hub. The snap ring on the front end of the countershaft is a selective lock ring and should be checked carefully for proper thickness on assembly.

Fig. 4 Detail of 2nd speed synchronizer

Reverse Idler Gear Bushings

If new bushings are required, press them into the gear from each end until flush with ends of gear. It is important that these bushings be staked as they are split bushings and may have a tendency to creep if not properly staked. When installed and properly staked, they must be line-reamed to size.

Transmission, Assemble

1. Install chip collector in bottom of case.
2. Assemble countergear front bearing spacer into case with its open side toward the outside and its edge flush with case.
3. Install countershaft assembly with rear bearing hub extending through rear bearing hole in case.
4. Install oil deflector and rear bearing on countershaft, using bearing retainer to drive bearing onto shaft. Lock bolts by bending tangs on lock plate.
5. Move countershaft forward into position. Rear bearing outer snap ring limits forward movement of countershaft.

59. Oil slinger

6. Place reverse idler gear into position and install shaft from rear to front, being careful to have slot in shaft in a horizontal position.
7. Drive idler shaft in until hole in shaft aligns with lock pin hole in case and install lock pin.
8. Install mainshaft so that rear of shaft protrudes out of rear bearing hole in case.
9. Install mainshaft rear bearing onto shaft.
10. Install mainshaft pilot bearing spacer on mainshaft pilot. Then install clutch gear synchronizer cone to pilot end of mainshaft and move mainshaft forward until clutch sleeve clears third speed gear on countershaft assembly.
11. Index cut-out portion of clutch gear teeth to obtain clearance over countershaft driven gear and install clutch gear assembly into case.
12. Install clutch gear bearing retainer, using new gasket. Apply Permatex or other suitable sealing compound to bearing retainer bolt threads, install bolts and tighten to 15-18 foot pounds.
13. Raise front end of mainshaft and enter pilot into mainshaft pilot rollers in clutch gear.
14. Using suitable pusher tool (J-2667) install mainshaft and bearing into case. Make sure three cut-out sections of fourth speed synchronizer cone align with three clutch keys in clutch assembly.
15. Install rear bearing retainer, using new gasket. Apply Permatex or other suitable sealer to retainer bolt threads and tighten bolts to 20-25 lb. ft. torque.
16. Place reverse shifter lever into position and thread lever bolt with bolt sleeve and flat washer through lever and into case from inside out. Tighten bolt to 25-30 lb. ft. torque. Install shift lever bolt nut and tighten to 60-65 lb. ft. torque. The sleeve is used under the head of the bolt to act as a shoulder for shifter lever to pivot on.
17. Install universal joint flange with speedometer drive gear on mainshaft. Lock transmission in two gears and tighten yoke retaining cap screw to 60-65 lb. ft. torque. Install speedometer driven gear in rear bearing retainer and tighten securely.

18. Make sure all transmission gears are in neutral and, using a new gasket, install cover assembly, being sure shifting yokes slide over their proper gears and that reverse shifter lever engages the reverse shifter head. Install cover attaching screws and tighten to 20-25 lb. ft. torque.
19. Check operation of transmission in all gears to be sure there is no indication of binding in any position.

CHEVROLET POWER DIVIDER & AUXILIARY 3 SPEED TRANSMISSION, 1956-59

This unit, Fig. 5, is a 3-speed auxiliary transmission combined in one gear box with a positive type power divider on tandem rear axle models. The gear box is mounted on cross supports to the frame forward of the rear axle.

Remove & Replace

1. Disconnect three control rods from shift rods at front of power divider.
2. Disconnect speedometer cable at right front of power divider.
3. Disconnect propeller shafts.
4. Support power divider on a suitable cradle and remove all mounting bolts.
5. Move unit to rear and down out of vehicle.
6. Reverse above procedure to install.

Disassemble, Fig. 5

1. Remove top cover.
2. Loosen lock screw in direct-low shift fork so fork will slide along rod.
3. Engage direct-low slide block into clutch teeth of low speed gear and push underdrive shift rod forward to engage underdrive slide block into clutch teeth of two-step gear. This locks gear from turning so U-joint flanges can be removed.
4. After removing U-joint flange, remove mounting clamp from front adapter.
5. Remove rear adapter and gasket.
6. Slip off U-joint flange spacers at rear of shafts.
7. Remove shift rods, forks and poppets. *If interlock balls prevent withdrawal of direct-low shift rod, adjust position of underdrive shift rod slightly to obtain complete release.*
8. Remove speedometer driven gear from cap and remove cap from front adapter.
9. Remove adapter, including front bearing and oil seal from case and off end of main drive gear.
10. Remove snap ring from main drive gear bearing and pull bearing and gear from case.
11. With block of hard wood held against rear of main drive shaft, tap shaft forward out of rear housing. Lift shaft, with slide block and pilot bearing, and pull forward out of underdrive gears.
12. Lift low speed and underdrive gears out top opening in case.
13. Remove secondary shaft front bearing cap. Support front of case and press shaft, front bearing and slide block out of rear bearing, gear and case.
14. Remove speedometer drive gear snap ring and slide gear and sleeve off shaft and remove Woodruff key. Then remove countershaft assembly.

Transmission, Assemble, Fig. 5

1. Place power divider case and rear bearing assembly with rear face on bench.
2. Set countershaft underdrive gear on bench with clutch teeth up and assemble slide block over clutch teeth with fork groove up. Place this assembly in case on top of rear countershaft bearing with slide block up.
3. Install two roller bearings in countershaft two-step gear and place this assembly in case on top of underdrive gear with large end of gear up.
4. Insert countershaft assembly from front of case, passing it through two-step gear and bearings, through underdrive gear and into rear bearing. Press bearing into case and shaft into rear bearing until there is approximately .010″ to .020″ end play between two-step gear and underdrive gear.
5. Turn case with top opening up and check slide block for full engagement with two-step gear and underdrive gear.
6. Install oil slinger against bearing on shaft. Place lockwasher on countershaft with internal tang in groove in shaft, and install nut finger tight against lockwasher.
7. Assemble flat washer on rear of countershaft with two capscrews. Hold shaft from turning with wrench on spanner lock nut and tighten two screws to a torque of 55 lb. ft.
8. Check for approximately .010″ to .020″ end play between two-step gear and underdrive gear.
9. Insert secondary shaft through top opening in case with clutch teeth toward front. Mesh gear with countershaft gear and against rear bearing.
10. Support inner race of rear bearing and install secondary shaft, with declutching slide block and front bearing assembled, through front of case, through gear and into rear bearing. Press assembly into place until shoulder on shaft seats against rear bearing.
11. Place main drive shaft underdrive gear inside and at rear of case with pilot flange toward front (internal splines recessed from edge).
12. Place puller gear with bearing and washers installed next to underdrive gear so clutch teeth are toward front of case.
13. Insert assembled main drive shaft through front of case, passing it through puller gear bearings, through underdrive gear and into rear bearing. Using a soft rod against forward end of shaft, press shaft into rear bearing.
14. Insert main drive gear and bearing assembly into front of case. Make sure pilot bearing on main drive shaft enters freely into drive gear pocket, then press front bearing into position with snap ring tight against case.
15. Check for approximately .010″ to .020″ end play between puller gear and main shaft underdrive gear.
16. Engage clutches and tighten nut on front end of countershaft, and lock with tang on washer. Check torque of screws on rear of countershaft which should be 55 lb. ft.
17. Place gasket on front adapter and bolt adapter to front of power divider case using the speedometer cap for locating only. *Do not bolt speedometer cap to adapter.* Tighten ½″ front adapter screws to a torque of 65 lb. ft.
18. Remove speedometer cap and place Woodruff key on countershaft. Slide speedometer gear and sleeve on countershaft with hub toward case and lock with snap ring.
19. Assemble speedometer cap with gasket in place and install on adapter. Tighten screws to a torque of 35 lb. ft. and install speedometer driven gear fitting.
20. With gasket in place, assemble front bearing cap-to-power divider case with ½″ screws and torque them to 55 lb. ft.
21. Install shift rods, forks, poppets, balls and springs.
22. Slip U-joint spacers on shafts at rear and, with gasket in place, bolt rear adapter to case, tightening screws to 70 lb. ft.
23. Assemble power divider front support bracket to front adapter.
24. Engage direct-low slide block into clutch teeth of low-speed gear and engage underdrive slide block into clutch teeth of two-step gear. This prevents the gears from turning when U-joint flanges are tightened.
25. Install mounting clamp on front adapter.
26. Push or tap three U-joint flanges on splined shafts. Install washers and nuts, tightening them to 280 lb. ft. torque.
27. Set slide blocks in neutral position. Line up lock screw hole in direct-low shift fork with hole in shift rod, install screw and lock with wire.
28. With gasket in place, attach top cover and tighten capscrews to a torque of 30 lb. ft.
29. Install drain plug and, after installing lubricant, install filler plug.

Automatic Transmission Section

For Allison Powermatic and Hydramatic transmissions used on Chevrolet, see the "name" chapters for service procedures

Fig. 1 Hydra-Matic throttle linkage. Conventional 6-cyl. models. 1954-59

HYDRA-MATIC DRIVE

For a detailed service procedure on repairing the Hydra-Matic transmission, see the Hydra-Matic chapter elsewhere in this manual. The following material outlines the procedure for adjusting linkage and removing the transmission from the truck.

THROTTLE LINKAGE, ADJUST

1954-59 Conventional 6-Cyl. Models

1. Adjust engine idle speed to 400-450 rpm.
2. Referring to Fig. 1, remove rod P from lever A and set lever A in adjusting position with Gauge J-5609.
3. Remove swivel C from lever B. Holding lever B back against stop in transmission, check distance between hole in lever B to back of transmission case with Gauge J-2545-C, Fig. 2. Bend lever B if required to allow entry of gauge in hole, using Tool J-5260, Fig. 3.
4. With lever B back against stop, adjust nuts D and E so swivel C just enters hole in lever B.
5. Remove gauge J-5609 and reinstall rod P to lever A.
6. With engine warm and idle adjustment set at 400-450 rpm, adjust nuts G and H so swivel J just enters hole in carburetor throttle lever.
7. Shorten rod F by loosening nut E two turns, then tighten nut D.
8. Remove swivel J from hole in carburetor lever and pull rod P upward

Fig. 2 Checking throttle lever position

Fig. 3 Use of tool for bending throttle lever

Fig. 5 Hydra-Matic throttle linkage. 1955-59 V8 models

Fig. 6 Powermatic accelerator and TV linkage. 1956-59 Models 5000, 7000

until linkage is stopped by the forward stop in transmission for lever B.

9. With rod P pulled up, bring accelerator pedal against toe pan stop with swivel M in place by adjusting nuts L and K. Then shorten accelerator pedal rod N by loosening nut L one turn and tighten nut K.
10. Replace upper end of rod P in carburetor lever at swivel J.

1954-59 Forward Control 6-Cyl. Models

1. Unfasten and remove engine cover.
2. Adjust engine idle speed to 400-450 rpm.
3. Referring to Fig. 4, remove rod N from lever O and set lever O in adjusting position with carburetor control lever Gauge J-5629. Slotted end of gauge rests on inside shoulder of hex head brass fitting on intake manifold and pin end fits in accelerator rod hole in lever O.
4. Remove swivel C from lever B. Holding lever B back against stop in transmission, check distance from hole in lever B to back of transmission case with Gauge J-2545-C, Fig. 2. Bend lever B if required to allow entry of gauge in hole, using Tool J-5260, Fig. 3.
5. With lever B back against stop, adjust nuts D and E so swivel C just enters hole in lever B. Then shorten rod F by loosening nut E two full turns and tighten nut D.
6. With carburetor idling at 400-450 rpm and engine warm, adjust nuts G and H so that swivel J just enters hole in carburetor throttle lever.
7. Remove gauge from lever O and manifold brass fitting. Pull rod P out of hole in carburetor throttle lever at swivel J and pull rod F up toward floor board until linkage is stopped by the forward stop on transmission for lever B.
8. With rod F pulled up, replace swivel M in lever O. Then adjust accelerator pedal against toe pan stop with swivel M in place by adjusting nuts L and K.
9. Replace rod P to carburetor at swivel J.
10. Shorten rod N by loosening nut L one full turn and tightening nut K.

Fig. 4 Hydra-Matic throttle linkage. Forward Control 6-cyl. models. 1954-59

1955-59 V8 Models

1. With carburetor at hot idle, and rod P removed from lever A, hold lever A back against transmission stop. Check distance from hole in lever A to back of transmission case with gauge shown in Fig. 2. Bend lever A if required to allow entry of gauge in hole, Fig. 3.
2. Adjust length of rod P to 15.60" and install in lever A, Fig 5.
3. Install rods E and H.
4. Loosen nut D 3½ turns and tighten nut B.
5. With stop screw F backed off, rotate lever G until linkage is stopped by full detent stop in transmission. Adjust screw F until it contacts bracket Q. Release lever G and advance screw F ½ to 1 full turn and lock.

Fig. 7 Powermatic accelerator and TV linkage. 1956-59 Models 6000, 8000

6. On 3100, 3200 and 3600 series only, install ⅛″ gauge pin through hole in lever L and bracket M. Install rod O to lever L and rotate lever L until stop screw F contacts bracket Q. Adjust length of rod O so swivel just enters lug on rod H.

Manual Control Linkage, Adjust 1954-59

Move shift control lever from N position to first detent you feel. In this position indicator should line up approximately with symbol 1-4. Check control lever in each of the other positions for indicator alignment. If alignment is not satisfactory, proceed as follows:

1. If gear shift control shaft upper support bracket is loose, tighten the clamp screw while holding the control lever firmly against the stop between 1-3 and 1-2 positions.
2. While holding control lever in 1-3 against the stop which prevents accidental shift into 1-2, loosen gear shift control rod swivel.
3. Make sure transmission outer shift lever is in three-speed drive position 1-3. Then tighten gear shift control rod swivel.

Neutral Safety Switch, Adjust

All trucks equipped with Hydra-Matic transmission are provided with a neutral safety switch which prevents operation of the starting motor except when the transmission is in Neutral position.

Place control lever in 1-4 position. With ignition off, operate starter control. If the starter operates, adjust as follows:

1. Loosen two switch mounting screws.
2. Place selector lever in Neutral and with clip over flats on end of shifter shaft, insert pin into switch mounting bracket and locating plate, Fig. 5.
3. Tighten screws to secure switch in this position and remove locating pin.

POWERMATIC ADJUSTMENTS, 1956-59

Accelerator & TV Linkage 5000 & 7000 Models

1. Referring to Fig. 6, install levers C and H and rods B and F (swivel on rod B should be installed in second hole from front of lever C).
2. Pull carburetor lever to wide open throttle position.
3. With rod J installed in lever H pull lever N forward to internal stop (full forward stop position).
4. Position swivel K on rod J so that it just enters upper hole in lever N. Tighten nuts against swivel K then back rear nut off 4½ full turns. Tighten swivel K against rear nut by tightening front nut. Install swivel K to lever N with clip.
5. Rotate lever C rearward through detent on rod B compressing spring on rod B until stopped by internal stop in transmission at lever N.
6. Position accelerator pedal down against toe pan stop and position clevis D on rod G so that it aligns with hole in lever C with lever on carburetor in wide open throttle position.
7. Holding pedal against stop, move clevis D forward (lengthening rod) on rod G 5 full turns. Tighten clevis D with lock nut.

6000 & 8000 Models

1. Referring to Fig. 7, place carburetor lever A in wide open position (rearward).
2. Install rod K to lever C.
3. Pull lever E forward tight against internal stop.
4. Position swivel P on rod K so it enters upper hole in lever E and tighten nuts against swivel.
5. Back off rear nut 3½ turns and tighten forward nut against swivel P.
6. Rotate lever B rearward through detent, compressing spring G until stopped by transmission internal stop at lever E.
7. Install rod J to lever D and adjust swivel M on rod J to enter hole in lever B with pedal F tight against toe pan stop.
8. Remove swivel M from lever B and turn swivel M clockwise 2 complete turns to shorten distance between ends.
9. Reinstall swivel M to top hole in lever B.

1956-57 9000 & 10000

1. Referring to Fig. 8, with carburetor in wide open position and transmission lever L forward against full detent stop, adjust swivel N on rod K to enter lower hole in lever L.
2. Back off rear 3½ turns and tighten forward nut against swivel N.

Fig. 8 Powermatic accelerator and TV linkage. 1956-57 Models 9000, 10000

Fig. 9 Powermatic accelerator and TV linkage. 1958-59 Models 9000, 10000

3. Compress detent spring E by rotating lever G rearward until lever L is stopped by internal stops in transmission (full forward detent position).
4. With accelerator pedal in contact with floor, adjust swivel F on rod H to attach rod H to lever C.
5. Turn swivel F approximately 6 turns clockwise to raise accelerator pedal free of floor. *On 9000 models, accelerator control rod has clevis at lever G. With pedal against stop and throttle lever through detent as in Step 3, adjust clevis to attach accelerator rod to lever G and tighten lock nut.*

1958-59 9000 & 10000

1. Referring to Fig. 9, with carburetor lever "A", rod "B", lever "C", lever "M", pedal "L" and lever "K" in place, proceed as follows:
2. Place lever "A" in wide open position (rearward—not through detent).
3. Install rod "F" to Lever "C".
4. Pull lever "K" forward tight against internal stop.
5. Position swivel "H" on rod "F", so it enters lower hole in lever "K".
6. In this position, back off rear nut at swivel "H" (3½ turns) and tighten front nut against swivel "H".
7. Again pull lever "K" forward tight against internal stop.
8. Install rod "D" to lever "M" and adjust swivel on rod "D" so pedal "L" is tight against floor mat.
9. Remove swivel from lever "C" and turn swivel clockwise 10 complete revolutions to shorten distance between ends.
10. Reinstall swivel to lever "C".

Fig. 10 Linkage adjustment. 1960-62 Powermatic

Hydraulic Retarder Linkage

The adjustment of the hydraulic retarder linkage requires that two conditions be met: *full apply* and *full release*. The only adjustment is located at the swivel clamp in the lower arm of the pedal bell crank under the toe board.

Before starting adjustment of the linkage, disconnect pedal rod from retarder cross shaft lever at lower front side of transmission and move shaft lever by hand to see if cross shaft is free and if retarder valve is hitting internal stops at both ends of its travel. The retarder valve moves ½" total travel and stops are sharp and positive. If cross shaft does not move freely, check for binding of shaft and be sure cross shaft support has spacers under each of three retaining bolts to transmission case. If cross shaft is very sloppy or loose, examine trunnions to see if nylon bushings are missing or broken.

To adjust retarder linkage, force retarder valve in to full travel against internal stop. Place $\frac{1}{16}$" to ⅛" thick shim between retarder pedal and its toe pan stop and hold pedal tightly against it Tighten clamp bolt on pedal apply rod. The shims under the pedal are used so that after adjustment the linkage lash will be compensated for by additional pedal travel.

Range Selector Linkage

The shift control linkage has only one adjustment. The geometry of the linkage is designed so that the only adjustment is on the swivel clamp at the bell crank lower arm. Place the shift tower shifter lever on the transmission full forward. Tighten clamp bolt. Shift slowly a few times to insure that the shift lever is not at the end of its travel at either end of the slot before the detent acts.

Neutral Safety Switch

To adjust the neutral safety switch, place shifter lever in Neutral, being

sure "V" formed by the two arms of the switch lever is pointed upward. Loosen front screw of two screws attaching switch bracket to tower support. Install 3/32" drill through hole in lower switch arm and bracket. Tighten bracket attaching screws securely. Remove drill from lever and bracket.

POWERMATIC LINKAGE, 1960-63

Control Linkage (Except Tilt Cab)

1. Insert a ¼" steel pin approximately 3" long through point "A", Fig. 10. This pin must pass through bosses on both sides of lever and a boss on the support bracket.
2. Place carburetor on hot idle stop and position TV rod full rearward against internal stop in transmission. To hold this rod in position a retaining wire must be inserted through the TV lever on the transmission and into a small hole on the transmission pan.
3. Insert swivel "B" on rod "X" into the accelerator control outer lever, then tighten compression nut. *Use the upper hole in the control lever for four barrel carburetor and the lower hole for the two barrel carburetor.*
4. Insert swivel "C" on the TV rod into the accelerator inner lever, then tighten compression nut.
5. If installed, remove the retaining wire from TV lever on transmission. Rotate accelerator control levers through detent. Adjust accelerator pedal rod at "D" so that surface "E" comes in full contact with floor mat. The L.C.F. accelerator rod attaches at rearmost hole on the inboard arm of the inner lever. All others attach to the lower hole of the outboard arm of the inner control lever. *If engine idles too fast after adjusting, recheck linkage adjustment. Be sure carburetor idle speed screw is fully off the fast idle cam throughout adjustment.*

Hydraulic Retarder Linkage

The adjustment of the hydraulic retarder linkage is fundamentally the same as hydraulic clutch pedal adjustment described in the Clutch Section. However, the hydraulic retarder pedal is adjusted to give ⅛" free pedal travel.

Once the pedal is adjusted, final adjustment of the hydraulic retarder control linkage is completed at the slave cylinder which actuates the hydraulic retarder valve at the Powermatic.

To adjust the slave cylinder, fully depress the slave cylinder push rod into the cylinder, then adjust the clevis on the push rod for free entry to the hydraulic retarder valve lever on the transmission.

Fig. 11 Powermatic linkage adjustment. 1961-63 Tilt Cab models

Tilt Cab Models

1. Insert a 3" long pin of ¼" diameter through two holes and notch, Fig. 11, to retain linkage in proper position.
2. With carburetor-to-lever rod clamp nut loose, place carburetor on normal idle stop and tighten clamp nut.
3. With clamp nut loose on transmission throttle valve rod and the TV lever on transmission held fully to the rear, tighten TV rod clamp nut.

Range Selector Linkage

The shift control cable is designed so the only adjustment is on the lower clevis at the transmission shift lever. Place the shift tower shifter lever in full "Lo" position, and the shift on the transmission full rearward. Adjust clevis on cable to insert clevis pin freely in hole in transmission shift lever and secure with cotter pin. Shift slowly a few times to insure that the shift lever is not at the end of its travel at either end of the slot before the detent acts.

Neutral Safety Switch

This adjustment is obtained in the same manner described for previous models.

POWERMATIC, REPLACE

1. Remove spark plug and disconnect battery ground strap.
2. Remove filter cartridge from transmission oil pan.
3. Remove control tower.
4. Disconnect throttle valve control rod from lever.
5. Disconnect retarder pedal rod from lever at transmission and unhook return spring from shaft at right side of transmission.
6. Remove oil filler tube and hose.
7. Disconnect oil cooler lines at brake valve body and warning signal wire from sender at top of oil line tee.
8. Disconnect speedometer driven shaft fitting from adapter.
9. Remove propeller shaft and bearing support, and hand brake assembly.
10. Remove flywheel underpan and, turning flywheel as necessary, remove flywheel-to-converter pump cover nuts.
11. Support rear of engine and remove converter housing-to-flywheel housing bolts.
12. Support transmission in suitable cradle and remove transmission mounting bolts.
13. Remove transmission rear support from frame, move transmission to rear slightly and lower from under vehicle.
14. Reverse the foregoing procedure to install the transmission.

Rear Axle Section

For Eaton and Timken (Rockwell-Standard) driving axles used on Chevrolet trucks, see the "name" chapters for service procedures and lubricant capacities

Chevrolet Axles & Lube Capacities

Axle Type	Rated Lbs. Capacity	Lube. Pints
Semi-floating	3300	4½
Semi-floating	3500	4½
Full-floating	5200	6½
Full-floating	7200	6½
Full-floating	11000	18
Full-floating	15000	19
Full-floating	17000	19
Two-Speed	15000	20
Two-Speed	17000	20

CHEVROLET SEMI-FLOATING AXLE, 1963

In these rear axles, Fig. 1, the rear axle housing and differential carrier are cast into an integral assembly. The drive pinion assembly is mounted in two opposed tapered roller bearings. The pinion bearings are preloaded by a spacer behind the front bearing. The pinion is positioned by a washer between the head of the pinion and the rear bearing.

The differential is supported in the carrier by two tapered roller side bearings. These bearings are preloaded by spacers located between the bearings and carrier housing. The differential assembly is positioned for proper ring gear and pinion backlash by varying these spacers. The differential case houses two side gears in mesh with two pinions mounted on a pinion shaft which is held in place by a lock pin. The side gears and pinions are backed by thrust washers.

Diff. Carrier Assy

Any major repairs on the differential carrier assembly, such as replacing the ring gear and pinion, calls for most accurate and precise adjustments of the assembly. Therefore, if the necessary tools and equipment are not available to do a first rate job, the carrier assembly should be exchanged for a new one, or the work should be farmed out to the truck dealer or to an auto parts jobber who has the facilities to do the work properly. For the guidance of those who are equipped to do this type of work, refer to Fig. 1.

Remove & Replace

Construction of the axle assembly is such that service operations may be performed with the housing installed in the vehicle or with the housing removed and installed in a holding fixture. The following procedure is necessary only when the housing requires replacement.

1. Raise vehicle and place stand jacks under frame side rails.
2. Remove rear wheels.
3. Support rear axle assembly with a suitable jack so that tension is relieved in springs and tie rod.
4. Disconnect tie rod at axle housing bracket.
5. Remove trunnion bearing "U" bolts from rear yoke, split universal joint, position propeller shaft to one side and tie it to frame side rail.
6. Remove axle "U" bolt nuts and allow control arm and shock absorbers to hang freely so that they do not interfere with axle. *On K Series trucks, remove spacer from axle housing.*
7. Disconnect hydraulic brake hose at connector on axle housing.
8. Remove brake drum and disconnect parking brake cable at lever and at flange plate.
9. Lower axle and remove from vehicle.
10. Reverse foregoing procedure to install axle assembly.

Fig. 1 Semi-floating rear axle of 3300 and 3500 lbs. rated capacity used on 1963 ½ ton trucks

Fig. 2 Semi-floating rear axle of 3300 and 3500 lbs. rated capacity used on ½ ton models prior to 1963

Axle Shaft, Replace

1. Raise vehicle and remove wheel and brake drum.
2. Drain lube from carrier and remove cover.

3. Remove differential pinion shaft lock screw and remove differential pinion shaft.
4. Pull flanged end of axle shaft toward center of vehicle and remove "C" lock from button end of shaft.
5. Remove axle shaft from housing, being careful not to damage seal.
6. Reverse foregoing procedure to install the axle shaft.

CHEVROLET SEMI-FLOATING AXLE, 1955-62

In these axles, Figs. 2 and 3, the drive pinion is mounted in two tapered roller bearings that are preloaded by a spacer. The pinion is positioned by a shim located between the head of the drive pinion and the rear pinion bearing. The front bearing is held in place by a large washer and a locking pinion nut.

The differential is supported in the carrier by two tapered roller side bearings. These bearings are preloaded by two threaded adjusting sleeves or ring nuts between the bearings and the pedestals. The differential assembly is positioned for proper ring gear and pinion backlash by varying the adjustment of these ring nuts. The ring gear is bolted to the case. The case houses two side gears in mesh with two pinions mounted on a pinion shaft which is held in place by a lock screw. The side gears are backed by thrust washers.

Fig. 3 Semi-floating rear axle of 3300 and 3500 lbs. rated capacity used on ½ ton models prior to 1963

Diff. Carrier Repairs

Any major repairs on the differential carrier assembly, such as replacing the ring gear and pinion calls for most accurate and precise adjustments of the assembly. Therefore, if the necessary tools and equipment are not available to do a first rate job, the carrier assembly should be exchanged for a new one, or the work should be farmed out to the car dealer or an auto parts jobber who has the facilities to do the work properly. For the guidance of those who are equipped to do this type of work, refer to Figs. 2 and 3.

Remove & Replace

It is not necessary to remove the rear axle assembly for any normal repairs. The axle shafts and carrier assembly can easily be removed from the vehicle, leaving the rear axle housing in place.

1. Remove axle shafts as explained further on.
2. Remove two trunnion bearing "U" bolts from rear universal joint and split joint. Lower propeller shaft to floor. Tape bearings to trunnion.
3. Drain lubricant after removing drain plug.
4. Remove sealing lock nuts that attach carrier to housing and remove carrier assembly.
5. Reverse foregoing procedure to install the differential carrier assembly and fill with lubricant to the filler plug hole.

Fig. 4 Full-floating rear axle of 5200 and 7200 lbs. rated capacity used on ¾ and 1 ton trucks prior to 1963

Axle Shaft, Replace

Several types of axle shaft bearings have been used. Some bearings have the seal mounted outboard while others have the seal mounted inboard. These various installations cannot accurately be applied to specific models. Therefore, when necessary to replace a bearing, examine the installation carefully and, if the new bearing is identical with the old, install it in the same way. However, should a roller bearing be installed where the original bearing was a ball type (or vice versa) follow the installation instructions contained in the bearing package.

Axle Shaft Removal

1. Raise car and place jack stands under rear axle housing.
2. Remove wheels and brake drums.
3. Remove four nuts and lockwashers from bearing retainer bolts (on inside of axle flange).
4. If bearing is a tight fit in axle housing, attach a slide hammer type axle shaft puller to hub bolts and remove axle shaft and bearing, Fig. 5. Be

Fig. 5 Full-floating rear axle of 5200 and 7200 lbs. rated capacity used on 1963 ¾ and 1 ton trucks

17. Adjusting Nut Lock
18. Differential Case—Right Half

careful not to disturb brake backing plate and inner gasket. *If bearing retainer and parking brake strut interfere raise strut slightly with screwdriver to obtain clearance.*

5. Install bolt and nut to hold backing plate and inner gasket to axle housing.

Axle Shaft Installation

1. Replace "O" ring seal in groove in bearing outer race. *When installing axle shaft with heavy duty bearing, spacer ring must be installed between bearing and axle housing bearing bore. Be certain chamfer on ring is installed toward center of vehicle.*
2. Install new retainer gasket.
3. Install axle shaft. Rotate shaft to align splines of shaft and differential side gear. Outer race of bearing must seat against shoulder in axle housing.
4. Secure bearing retainer with nuts and lockwashers, install brake drum gasket, drum, wheel and hub.
5. Lower vehicle to floor and road test for leaks and noise.

CHEVROLET FULL FLOATING AXLES

Light Duty Type, 1955-62, Fig. 4

In these axles the drive pinion is straddle-mounted, being supported at the rear end on a straight roller bearing and at the front by a tapered roller bearing composed of two inner cone and roller assemblies with a one-piece outer race for both bearings. The outer race is drilled between the bearings to provide lubrication.

The ring gear is bolted to the differential case and is provided with a ring gear thrust pad to prevent distortion when starting under heavy loads. The axle also has a four pinion differential. Barrel roller bearings are used to mount the differential case in the carrier.

Light Duty Type, 1963, Fig. 5

In these axles the straddle mounted drive pinion is supported at the front by a one-piece double row ball bearing. The pinion rear bearing is a roller bearing assembly with a precision ground diameter on the pinion pilot which functions as an inner race. Some models utilize a two pinion differential while others have a four pinion differential.

Medium and Heavy Duty Types, Figs. 6, 7

These axles have a straddle-mounted drive pinion which is supported at the rear by a straight roller bearing. The pinion front bearing consists of a double row ball on the medium duty axles and two opposed tapered roller bearings on the heavy duty models. Selective shims placed between front bearing and its seat in the carrier housing provide a means of adjusting pinion depth to attain correct ring gear and pinion tooth contacts.

The differential is a four pinion type. Thrust washers are used between the side gears and case and also between differential pinions and case.

A thrust pad mounted on the end of an adjusting screw threaded into the carrier housing limits deflection of the ring gear under high torque conditions.

AXLE SHAFT, REPLACE

5200 & 7200 Lb Axles

1. Remove bolts that attach axle shaft flange to wheel hub.
2. Install two ½-13 bolts in the threaded holes provided in the axle shaft flange. By turning these bolts alternately the axle shaft may easily be started and then removed from housing, Fig. 8.
3. Thoroughly clean both axle shaft flange and end of wheel hub. *Any lubricant on these surfaces tends to loosen axle shaft flange bolts.*
4. Place a new gasket over axle shaft and position axle shaft in housing so that shaft splines enter differential side gear. Position gasket so that holes are in alignment and install flange-to-hub attaching bolts. Torque bolts to 85-95 ft-lbs. *Note: To prevent lubricant from leaking through flange holes apply Permatex to bolt threads. Use care in the amount of sealer applied. If the application is too heavy, the sealer may be forced out as the bolt is installed and may destroy the sealing effect of the flange-to-hub gasket.*

11,000 & 15,000 Lb. Axles

1. Remove hub cap and install the tool shown in Fig. 9 in tapped hole in shaft flange.
2. Install slide hammer and remove axle shaft.
3. Remove all old gasket material from hub and hub cap. Clean shaft flange and mating surfaces in wheel hub.
4. Install axle shaft so that flange splines index into hub splines. Tap shaft into position.
5. Install new hub cap-to-hub gasket, position cap to hub and install attaching bolts. Torque bolts to 11-18 ft-lbs.

17,000 Lb. Axles

1. Remove axle shaft flange-to-hub retaining nuts.
2. Strike center of shaft flange with a lead hammer to loosen flange and dowels.
3. Remove tapered dowels from studs and pull axle shaft from housing. It may be necessary to spread dowels to permit removal.
4. Clean old gasket material from wheel hub and axle shaft flange and install a new gasket over hub studs and against hub.
5. Install axle shaft so that splines are aligned with differential side gear and flange holes index over hub studs.

6. Install tapered dowel over each hub stud. Install and tighten stud nuts to a torque of 80-100 ft-lbs.
7. See that clearance exists between face of stud nuts and axle shaft flange. If no clearance exists, it indicates excessive wear at studs, tapered dowels or flange holes. Replace worn part if necessary.

WHEEL BEARINGS, REPLACE

Hub & Drum, Remove

1. Remove wheel and axle shaft.
2. Disengage tang of nut lock from slot or flat of lock nut, then remove lock nut from housing tube, using appropriate tool, Fig. 10.
3. Disengage tang of nut lock from slot or flat of adjusting nut and remove nut lock from housing tube.
4. Use appropriate tool, Fig. 10, to remove adjusting nut from housing tube. *On 5200 and 7200 axles, remove thrust washer from housing tube.*
5. Pull hub and drum straight off axle housing, using care on 11,000, 15,000 and 17,000 lb. axles to avoid dropping outer bearing inner race and roller assembly. *Note: on 15,000 lb. axle, remove inner bearing race and inner bearing oil seal from axle housing and discard seal.*

Bearing Cup, Replace

Replace inner cup (all axles) and outer bearing cup for 17,000 lb. axles as follows:

1. Cut a suitable length of ½" steel bar stock for press-out tool as shown in Fig. 11.
2. Place appropriate press-out tool behind bearing cup, index tool in notches provided, and press out cup with an arbor press.
3. Position bearing cup in hub with thick edge of cup toward shoulder in hub. Then, using applicable cup installer, press cup into hub until it seats on hub shoulder. Make certain cup is not cocked and that it is fully seated against shoulder.

Outer Bearing, Replace

Replace outer bearing on all axles except 17,000 lb. axle as follows. The inner bearing must be removed before attempting to replace the outer bearing.

1. Using a punch of suitable length, tap bearing outer race away from bearing retainer ring, Fig. 12. Then remove retaining ring from hub, Figs. 12 and 13.
2. Press bearing from hub, Figs. 14 and 15.
3. Place axle shaft spacer (11,000 and 15,000 lb. axles) and inner race and roller assembly in hub with larger O.D. of roller assembly toward outer end of hub. Then position bearing cup in hub with thin edge of cup toward outer end of hub. Press cup into hub until clearance is obtained for retainer ring installation.
4. Install retainer ring. Then press bearing cup into positive contact with retainer ring. *Note: The bearing cup-to-retainer ring seating procedure is essential to assure that an accurate wheel bearing adjustment will be obtained, and that the adjustment will not loosen up during subsequent vehicle operation.*

16. Differential Bearing Adjusting Nut
17. Adjusting Nut Lock
18. Differential Case—Right Half

WHEEL BEARINGS, ADJUST

Before checking wheel bearing adjustment, make sure brakes are fully released and do not drag. Check bearing play by grasping tire at top and pulling back and forth or by using a pry bar under tire. If bearings are properly adjusted, movement of brake drum in relation to brake flange plate will be barely noticeable and wheel will turn freely. If movement is excessive, adjust bearings as follows:

1. Remove axle shaft and raise vehicle until wheel is free to rotate.
2. Disengage tang of nut lock from lock nut and remove them from axle housing tube.
3. Using appropriate tool, tighten nut to specifications given below, at the same time rotating hub to make sure that all bearing surfaces are properly seated. Then back off adjusting nut one flat or notch.
   a. On 5200 and 7200 axles, tighten adjusting nut to 50-60 ft-lbs. and back off nut ⅛ turn to align nearest slot with short tang on nut lock.
   b. On 11,000 lb. axle, tighten adjusting nut to 75-100 ft-lbs. and back off nut ⅛ turn to align nearest slot with short tang on nut lock.
   c. On 15,000 lb. axle, tighten adjusting nut to 75-100 ft-lbs. and back it off to align nearest slot with short tang on nut lock.
   d. On 17,000 lb. axle, tighten adjusting nut to 65 ft-lbs. and back it off $\frac{1}{16}$ to ¼ turn to align slot with short tang on nut lock.
4. Insall nut lock.
5. Make sure wheel turns freely. Then install lock nut and tighten to specifications given below. Bend tang of nut lock over flat or slot of lock nut.
   a. On 5200 and 7200 lb. axles, tighten lock nut to 175 ft-lbs.
   b. On 11,000 and 15,000 lb. axles, tighten lock nut to a minimum of 250 ft-lbs.
   c. On 17,000 lb. axles, tighten lock nut to 135 ft-lbs.
6. Lower vehicle and install axle shaft.

DIFFERENTIAL CARRIER

Major operations on the differential carrier assembly may be performed without removing the rear axle assembly

Fig. 7 Full-floating rear axle 15,000 and 17,000 lbs. rated capacity used on 2 and 2½ ton trucks

Fig. 12 Removing bearing retainer. 5200 and 7200 lb. axles

Fig. 13 Removing bearing retainer ring. 11,000 and 15,000 lb. axles

from the vehicle. After removing the axle shafts, remove the differential carrier assembly from the axle housing.

To facilitate adjusting of pinion depth in the ring gear, there are four shims available for service use. They are .012, .015, .018 and .021″.

If the orginal ring gear and pinion are to be used, it is advisable to replace the same thickness of shims in the carrier housing counterbore that were removed.

If a new ring gear and pinion are used, one .021″ shim should be used as a standard starting setup.

Checking Pinion Depth

Note—Details on tooth patterns and method of checking ring gear and pinion backlash are given in the Timken and Eaton axle chapters. Backlash between ring gear and pinion in Chevrolet axles are .003-.006″ on 5200 lb. axles and .005-.008″ on all others.

1. Coat the ring gear teeth lightly with red lead or prussian blue. Then turn the pinion shaft several revolutions in both directions.
2. If the pinion depth is correct, the tooth pattern will be centered on the pitch line and toward the toe of the ring gear.
3. If the pattern is below the pitch line on the ring gear teeth, the pinion is too deep and it will be necessary to remove the pinion assembly and increase the shim thickness between pinion bearing and carrier.
4. If the pattern is above the pitch line on the ring gear teeth, the pinion is too shallow and it will be necessary to remove the pinion and decrease the shim thickness between pinion bearing and carrier.

Fig. 8 Removing axle shaft. 5200 and 7200 lb. axles

Fig. 9 Removing axle shaft. 11,000 and 15,000 lb. axles

Fig. 14 Removing hub outer bearing. 5200 and 7200 lb. axles

5. Changing the pinion depth will make some change in backlash; therefore, it will be necessary to readjust the backlash.

Ring Gear Thrust Pad, Adjust

After the differential carrier is assembled and properly adjusted, install the thrust pad and tighten the adjusting screw until the bronze tip engages the back of the ring gear while the gear is rotated. Back off the screw 1/12 turn and tighten lock nut, Fig. 16. Make sure screw does not turn during the locking process.

CHEVROLET TWO SPEED AXLE

Manufactured by Chevrolet this unit, Fig. 17, is offered as an option in both the 15,000 and 17,000 lb. capacities. Torque is transmitted through the differential case through eight teeth on the four planetary pinions. The primary gears are hypoid type. The straddle-mounted drive pinion and ring gears operate to produce the high range reduction, the planet and sun gears being locked to revolve with the ring gear.

Fig. 15 Removing hub outer bearing. 11,000 and 15,000 lb. axles

A positive, quick acting, two-way vacuum system actuates the shift collar and sleeve. The hand control is located on the gear shift lever, permitting simultaneous transmission and axle shifts so that full advantage may be taken of all forward ratios.

Whenever service on the vacuum shift system becomes necessary the push rod should be adjusted so that the distance between the outer faces of the stop washers on the push rod should be 3½″ as shown in Fig. 18.

Fig. 16 Ring gear thrust pad adjustment

Differential Carrier Removal

1. Use slide hammer to pull axle shafts out about 8″ to clear differential.
2. Remove vacuum cylinder hoses.
3. Split rear universal joint and slide propeller shaft forward and swing out of the way.
4. Before removing all the carrier-to-housing attaching bolts, install a long drift through one of the upper holes to support the carrier.
5. When all attaching bolts are removed, slide a roller jack under the carrier and wheel it out from under the truck.

Disassembly, Fig. 19

1. Remove anchor from left side of carrier.
2. Remove vacuum shifter assembly.
3. Drive out shifter yoke shaft.
4. Slide shifter yoke and sleeve to the left, removing these parts from end of sun gear.
5. Remove adjusting nut locks.
6. Remove oil trough.
7. Remove ring gear thrust pad.
8. Remove bearing caps and adjusting nuts.
9. Remove differential and planet assembly from housing, using care to see that differential side bearing outer races are not dropped.

Pinion Disassembly

1. Referring to Fig. 20, loosen pinion bearing oil seal retainer bolts.
2. Tap on deflector flange with soft

Fig. 17 Cross section of Chevrolet two-speed axle

Fig. 18 Adjusting vacuum shift push rod

Fig. 19 Exploded view of differential and planet assembly

Fig. 20 Exploded view of pinion assembly

hammer, driving out pinion assembly gradually from carrier housing while continuing to remove the pinion oil seal retainer bolts.

3. Remove shims from carrier housing, noting the number and thickness of shims present in back of double thrust bearing. *If flange is removed from pinion a slide hammer may be used to pull pinion out of housing.*
4. Remove rear pinion bearing.
5. If not already removed, separate flange from pinion.
6. Remove pinion oil seal retainer and seal.
7. Press double thrust bearing off pinion.
8. Press inner race off end of pinion.

Pinion Assembly

Reverse the disassembly procedure to assemble the pinion. Apply a torque of 160-280 lb. ft. on the pinion nut and install cotter pin. *Do not loosen nut to install cotter pin; if necessary tighten nut until cotter pin can be installed.*

Install pinion bearing shims in carrier housing and install pinion by tapping on flange until assembly is in far enough to start retaining bolts. This procedure is necessary since the retaining bolts interfere with the deflector on the flange until they are threaded in several turns. Tighten bolts to 90-100 lb. ft.

If it is possible to measure any amount of "in and out" movement of the pinion assembly at this point, remove the pinion assembly and check for the following: (a) pinion nut drawn down to 160-280 lb. ft. torque; (b) pinion bearing preload (15-25 in. lb. for new bearing, 5-15 in. lb. if used parts); (c) one pinion depth adjusting shim installed and in place.

Differential and Planet Disassembly

1. Mark ring gear, differential, planet support case and case cover for alignment by scribing or marking lines on case, cover and gear.
2. Remove planet cover, sun gear and planet gears. *Mark or tag all gears so that they may be reassembled exactly as removed. Planet gears are supplied only as a set.*
3. List differential and planet support off case cover.
4. Separate planet support and cover. *These parts are stamped on all four sides with matching numbers to assist in assembly.*
5. Remove spiders, gears and thrust washers. *Mark or tag all parts for reassembly exactly as removed.*
6. Remove side gears and thrust washers.
7. Remove differential side bearings.

Differential and Planet Assembly

Reassembly is the reverse of disassembly. The side gear with the longest hub belongs on the side nearest the ring gear. Install side gear thrust washers before installing side gears. Tighten differential and planet cover to a torque of 70-110 lb. ft.

The four planet gears are installed on the journals with the large chamfer on the I.D. of the gear toward base of journal.

Be sure to assemble the ring gear, differential, planet support case and cover according to the marks prior to disassembly. Tighten attaching screws to a torque of 85-95 lb. ft.

Ring Gear and Pinion, Adjust

1. With the differential assembled and installed in the carrier housing, proceed as follows:
2. Loosen right hand adjusting nut and tighten left hand adjusting nut. Use a spanner wrench on the right side and a drift and hammer on left side.
3. Continue tightening left hand nut until all backlash between ring gear and pinion is removed.
4. Back off left hand nut approximately two notches to a point where notch in nut is aligned with lock.
5. Tighten right hand nut firmly to force differential and planet in solid contact with left hand adjusting nut. Loosen right hand nut until it is free of its bearing, then retighten snugly against bearing. Tighten right hand nut from one to two notches more to a position in which a notch in nut aligns with lock. This method provides for the proper preload of bearings.
6. Mount a dial indicator on the housing and check backlash between ring gear and pinion which should be .003″ to .012″ (.005″ to .008″ preferred). If backlash is more than .012″ loosen right hand adjusting nut one notch and tighten left hand nut one notch If backlash is less than .003″, loosen left hand nut one notch and tighten right hand nut one notch.

Checking Pinion Depth

Check the pinion depth by coating the ring gear teeth with red lead or prussian blue and determine depth as outlined in the *Timken and Eaton Axle Chapters.*

Final Assembly

1. Install ring gear thrust pad and tighten until the pad contacts the ring gear, then back off 30 degrees (1/12 turn) to obtain a clearance of .005″ to .007″ and tighten lock nut.
2. When installing shifter mechanism, install splined end of shifter yoke to rear of differential. The end of shifter lever shaft must be flush with the lever hub to avoid binding when the vacuum shifter assembly is installed.
3. Install the carrier assembly into the axle housing and tighten attaching cap screws to a torque of 55-60 lb. ft.

Four Wheel Drive

For service procedure on the transfer case used with four-wheel drive trucks, see the Transfer Case Chapter

FRONT AXLE

1960-63

The front axle is a Spicer unit equipped with steering knuckles, Fig. 1. The differential carrier assembly is of similar design to the rear axle used on 1963 ½ ton trucks.

1957-59

The front axle is equipped with constant velocity universal joints. The differential carrier assembly is identical to the full-floating rear axle differential carrier used on ¾ ton trucks. Fig. 2 illustrates the construction of the constant velocity universal joints.

TOE-IN ADJUSTMENT

1957-59

The tie rod ends, Fig. 3, have a coarse thread on one end and a fine thread on the other end to permit accurate toe-in adjustment. *Caster and camber are inherent in the axle design and need not be adjusted.*

Toe-in checking procedures are the same as for Conventional models except that toe-in specifications are $\frac{1}{32}''$ to $\frac{5}{32}''$. Specified toe-in may be obtained by backing off or turning on the tie rod end, Fig. 2. One turn of the tie rod with fine thread affects the toe-in by approximately ¼", while one turn of the tie rod end with the coarse thread affects the toe-in by $\frac{9}{32}''$. *If tie rod and ends were disassembled from the axle, set the tie rod end centers initially at 49⅞" before taking measurements* (see Fig 4).

23. Drive Flange

KINGPIN TRUNNION BEARING

Front axle trunnion bearing adjustment is necessary only when there is excessive play in the steering system, irregular wear on tires or persistent loosening of the tie rod.

1. Raise front end of truck and place jack stands behind front springs.
2. Disconnect drag link and tie rod to allow independent movement of each steering knuckle.
3. Apply torque wrench to bearing retainer bolt and check torque necessary to turn steering knuckle. Knuckle should turn easily but have no play with 120-180 inch pounds torque.
4. If torque is too low, remove bearing retainer and remove shims up to .005".
5. Reinstall retainer, tighten bolts to 30-40 ft. lbs. and recheck torque necessary to turn knuckle.
6. If there is still excessive play, repeat Steps 3, 4 and 5. *Do not remove shims in excess of .010". If there is still excessive play after removing .010" shim, the steering knuckle should be disassembled and inspected for wear or damage.*

FREE WHEELING HUBS

1957-59

The purpose of the free wheel hubs, Fig. 5, is to reduce friction and wear by disengaging the front axle shafts, differential and drive line from the front wheels when the vehicle is operated under conditions where the front wheel drive is not needed. The engagement and disengagement of the free wheel hubs is a manual operation which must be performed at each front wheel. Both hubs must be in the fully locked or fully unlocked position. They must not be in the free wheeling position when low all wheel drive is used as the additional torque output in this position can subject the rear axle to severe strain and rear axle failure will result.

The hub is serviced as a unit and may be removed and installed as outlined below.

Removal

1. Turn hub key to set hub all the way to the "free" position.
2. Remove nuts retaining hub cap to wheel hub and remove clutch gear ring, cap and screw assembly; then remove drive pins and gasket from body or cap.
3. Remove snap ring from end of axle shaft.
4. Pull drive flange, body and bearing assembly from shaft and studs. Remove shim from studs, if present.

Fig. 2 Front axle details. 1957-59 Four Wheel Drive

11/32 Toe-in		1 On	0	3/32
3/8 Toe-in		0	1 On	3/32

Fig. 4 Toe-in correction table

Disassembly

1. Remove clutch gear ring from cap and screw assembly.
2. Remove snap ring from body and separate flange, body and bearing.
3. Wash all parts, blow dry and inspect for wear or damage.

Assembly

1. Lubricate clutch gear ring and install on screw all the way into cap.
2. Lubricate bearing and install in body.
3. Brush a small amount of lubricant on flange and install in body and bearing.
4. Install snap ring in flange to retain bearing.

Installation

1. Install shim, if needed, on wheel hub and slide flange, body and bearing assembly over studs and onto splines of axle shaft; then install snap ring on end of shaft.
2. Add shims .010″ at a time, to a maximum of .030″, until sufficient to prevent contact between interior surface of axle housing ball end and ball joint housing, but not so thick as to cause excessive wear to the spindle bushing or interfere with the installation of snap ring.
3. Install drive pins in body and install gasket on body.
4. Lubricate drive pins and clutch screw and install clutch gear ring, body and screw over studs and pins.
5. Install retaining nuts and tighten to a torque of 18-20 lbs. ft.

1961-63

Removal

1. Turn hub key to set hub "free" or disengaged position.

Fig. 5 Free-wheeling hub. 1957-59

1. Shim
2. Body
3. Gasket
4. Drive pin
5. Snap ring
6. Clutch gear ring
7. Cap
8. Screw and key ass'y

Fig. 6 Front free wheeling hub installation. 1961-63 Four wheel drive

2. Remove outer clutch ring, cap and cam assembly as follows, Fig. 6.
   a. On models with type of hub shown in upper view, Fig. 6, remove internal snap ring from hub and pull assembly out of hub.
   b. If the type hub shown in lower view, Fig. 6, is used, remove bolts retaining hub cap to hub, pull assembly and extension housing away from hub and remove gaskets.
3. Remove snap ring from end of axle shaft.
4. Pull bearing and inner clutch ring assembly from shaft.

Disassembly

1. Turn key to engaged position to release pressure from springs.
2. With suitable drift punch, remove key knob retaining pin through holes in outer clutch gear.

Fig. 7 Front wheel details on 1957-59 ¾ and 1 ton models

3. Lift key knob and retaining flange from inner clutch gear springs.

Assembly

1. All parts should be cleaned and lubricated during assembly to prevent deterioration before unit is placed in service. Replace all gaskets and "O" rings.
2. Place springs in holes in clutch gear.
3. Place retaining flange down over springs, lining up "locking or aligning" pin in position hole.
4. Install key knob into center of assembly and install retaining pin.

Installation

1. Place bushing and inner clutch ring over axle spline with clutch teeth outward. Slide on until bushing bottoms in wheel hub and install snap ring in axle shaft.
2. Install outer clutch ring and cam assembly as follows, referring to Fig. 6.
   a. On models with type of hub shown in upper view, Fig. 6, start assembly straight into hub, taking care to work "O" ring past snap ring groove in hub. Install snap ring in hub.
   b. If type of hub shown in lower view, Fig. 6, is used, place gasket on hub, align mounting holes in clutch ring and cap with holes in hub and install bolts and lockwashers.
3. Turn knob to check for proper locking.

FRONT AXLE

Remove and Install

1. Disassemble propeller shaft from front axle differential.
2. Raise front of truck and support it with jacks behind front springs.

Fig. 9 Assembly of axle shaft and U-joint. 1957-59

3. Disconnect drag link from steering arm.
4. Disconnect brake hoses from frame fittings.
5. Disconnect shock absorbers from spring clamp plate or axle brackets.
6. Separate axle from truck springs.
7. Roll front axle from under truck.
8. Install in reverse order of removal.

AXLE SHAFT, REPLACE

1957-59 ½ Ton Models

1. Raise truck and remove wheel.
2. Remove drive flange nuts, Fig. 7.
3. Remove snap ring retaining drive flange to axle shaft.
4. Remove drive flange and shim. *Two tapped holes are provided in flange to enable studs to be installed to force drive flange from shaft in event of tight fit. If necessary to use these holes, remove and save protective plastic plugs.*
5. Remove outer lock nut.
6. Remove lock with hooked wire or similar instrument; then remove inner lock nut.
7. Slip hub off spindle.
8. Remove brake and spindle.
9. Remove axle shaft and U-joint.
10. Install by reversing removal procedure.

1957-59 ¾ and 1 Ton Models

1. Jack up truck and remove wheel.
3. Remove snap ring retaining drive flange to axle shaft on all except dual rear wheel installations.
4. Remove drive flange and shim. *Two tapped holes are provided in flange to enable studs to be installed to force drive flange from shaft in event of tight fit. If necessary to make use of these holes, remove and save protective plugs.*
5. Remove outer lock nut, lock and inner lock nut.
6. Remove drum and hub.
7. Remove brake and spindle mounting nuts and remove slinger.
8. Remove axle shaft and U-joint.
9. Install by reversing removal procedure.

Fig. 8 Disassembly of axle shaft and U-joint. 1957-59

1960-63

1. Support vehicle with front wheel free.
2. Place drain pan under wheel and remove hub grease cap.
3. Remove snap ring from axle shaft.
4. Remove drive flange as follows:
   a. On K10 models, pull splined drive flange from shaft and hub and remove spacer from hub.
   b. On K20 models, remove stud nuts and washers, drive flange and gasket.
5. Remove bearing lock nut, lock ring and adjusting nut.
6. Remove wheel, hub and drum as a unit.
7. Remove bolts holding brake flange plate and spindle to steering knuckle.
8. Remove flange plate from steering knuckle and support plate so brake hose will not be damaged.
9. Slide spindle from shaft.
10. Remove axle shaft and joint assembly.
11. Reverse foregoing procedure to install. However, adjust wheel bearings by tightening the nut using a T-handle wrench (12" long on each side). Rotate drum and tighten snug. Loosen nut 45 degrees and assemble lockwasher by loosening nut to nearest hole, then assemble outer nut. Tighten nut to 40 ft-lbs. minimum.

U-JOINT REPAIRS

1957-59

1. Clean grease from parts.
2. Hold axle shaft as shown in Fig. 8 and rap face of joint sharply against protected vise or edge of bench. *This causes snap ring on end of axle shaft to contract and permit shaft and joint to separate.*
3. Tilt race and cage and remove balls.
4. Align race and cage and pull these parts from ball housing.
5. Disassemble cage from race.
6. Examine all parts for wear and damage.
7. Replace worn parts and assemble in reverse order of disassembly, assembling joint to axle shaft as shown in Fig. 9.

1960-63

The universal joints used on these models are the conventional cross and roller type.

STEERING KNUCKLE

1957-59

1. Remove front axle shaft.
2. Remove upper and lower bearing cap and shims.
3. Cut lock wire on front and rear seal retainer bolts at inner side of knuckle housing and remove seal retainers and seals, Fig. 10.
4. Drive roll pins from flanges of upper and lower knuckle housings.
5. Separate upper and lower housings.
6. Tap bearing cups from housings.
7. Pull bronze bearing from upper trunnion and remove key.
8. Remove bearing from lower trunnion.
9. Reverse procedure to assemble and install. *However, when installing bearings, install .010" shims at each bearing. Install bearing cap and tighten bolts to 50-60 lbs. ft. torque. Apply torque wrench to bearing cap bolt and check torque necessary to turn steering knuckle. Knuckle should move easily but have no play with 14-20 lbs. ft. torque. Ideal torque is 15-16 lbs. ft. If not within limits, remove lower bearing cap and add shims to decrease torque or remove shims to increase torque.*

1960-63

1. Remove axle shaft and U-joint.
2. Disconnect steering rod from steering arm.
3. Disconnect tie rod from steering knuckle.
4. Remove seal retainers (2 pieces) from knuckle.
5. Remove felt seal, rubber seal and seal ring from knuckle and let them hang on axle housing.
6. Remove upper and lower bearing retainers and shims from knuckle.
7. Remove knuckle from housing and remove bearing cones from axle housing.

Installation

1. Install bearing cones and bushings in cups in axle housing.
2. Place steering knuckle over axle housing yoke and install bearing retainers. Use same shims removed, or equivalent amount, and tighten bearing retainer bolts and nuts to 25 ft-lbs. torque. *On K20 models, position key in kingpin and install in bushing by aligning kingpin and key with keyway in bushing.*
3. Check bearing preload as follows:
   a. On 44-5F models, use a spring scale positioned in the tie rod hole. Knuckle should turn with 11-20 lbs. pull. Add shim to decrease preload; remove shim to increase preload.
   b. On 44-5HDF models, use a torque wrench positioned on upper bearing retainer nut. Knuckle should turn with a 15-35 ft-lbs. torque load. Adjust preload by increasing or decreasing shim packs at lower bearing only. Upper shim pack should be .060" thick.
4. Position seal ring, rubber seal and felt seal against inboard face of knuckle and align bolt holes. Install seal retainer (2 pieces).
5. Connect steering rod and install axle shaft.

Fig. 10 Steering knuckle housing. 1957-59

WHEEL BEARINGS, ADJUST

10 Series

1. Remove wheel and tire.
2. Remove dust cap from end of hub and remove spindle cotter pin.
3. Tighten adjusting nut to 15 ft-lbs while rotating hub in both directions.
4. Back off nut one flat and insert new cotter pin. If nut and spindle hole do not line up, back off slightly to align hole.
5. Spin hub to make sure it turns freely and install dust cap and wheel assembly.

20-30 Series, I Beam 50-60 Series (Except S69, T60, T60H)

1. Remove wheel assembly, hub dust cap and spindle cotter pin.
2. Tighten adjusting nut to 40 ft-lbs torque while rotating wheel in both directions.
3. Back off nut ⅓ turn and install cotter pin. If spindle hole does not line up, tighten nut until alignment is obtained.
4. Spin hub to make sure it turns freely. Lock cotter pin, install hub dust cap and wheel assembly.

I Beam, P20-30 Series

1. Remove wheel assembly, hub dust cap and spindle cotter pin.
2. Tighten adjusting nut to 33 ft-lbs while rotating wheel in both directions.
3. If a slot in nut lines up with either of two holes in spindle, back off nut 1/6 turn until next slot lines up with next hole and insert cotter pin. If there was no alignment after tightening nut, back off until slot lines up with nearest hole in spindle and insert cotter pin. *Note: At all times nut should be backed off no more than 1-6 turn.*
4. Install hub dust cap and wheel.

I Beam 80 Series, S69, T60, T60H

1. Remove wheel assembly, hub dust cap and spindle cotter pin.
2. Tighten adjusting nut to 60 ft-lbs while rotating hub in both directions.
3. Back off nut ⅓ turn and install cotter pin. If spindle hole does not line up, tighten nut until alignment is obtained.
4. Spin drum to make sure it rolls freely. Lock cotter pin, install hub plate or cap and wheel assembly.

Front End & Steering Section

WHEEL ALIGNMENT

1963 Coil Spring Suspension

Caster and camber adjustments are made by means of shims located between upper control arm shaft and mounting bracket attached to suspension crossmember. A series of convex and concave spacers with flat opposite sides are used. These spacers allow a positive cross shaft-to-bracket attachment regardless of the number of shims used. Shims may be changed at either front or rear to vary caster, or at both points to vary camber.

Caster

1. Measure frame angle at "B", Fig. 1.
2. Check caster on alignment machine.
3. Add angle "B" and caster angle to determine *frame corrected angle.*
4. Measure dimension "A", Fig. 1.
5. Using dimension "A" and chart for appropriate vehicle, Fig. 2, find recommended caster angle.
6. The frame corrected angle should correspond to the recommended angle on the chart within plus or minus ¼ degree. Make necessary changes to bring caster angle within limits.

Camber

1. Measure camber on alignment machine.
2. Measure dimension "A", Fig. 1.
3. Using dimension "A" and chart for appropriate vehicle, find recommended camber angle.
4. If angle in Step 1 does not correspond to the recommended angle in the chart within plus or minus ¼ degree, make necessary changes.

Fig. 1 Caster-camber adjustment. 1963 coil spring suspension

Fig. 2 Caster-camber chart. 1963 coil spring suspension

1960-62 Torsion Bar Suspension

10 to 40 Series

Caster and camber adjustments are made by means of shims between the upper control arm spacer and the bracket attached to the frame. Shims may be changed at either front or rear bolt to change caster or at both points equally to change camber.

To reduce the number of shims that have to be handled, use .0598″ or .1196″ shims. The shim pack should not exceed ⅝″ (twenty one .0299″ shims). The total difference in shims between the front and rear bolts should not exceed .33″ (eleven .0299″ shims).

For caster changes, one shim added to the rear bolt changes caster —2/5° and camber —1/60°. One shim removed from the rear bolt changes caster +2/5° and camber —1/30°.

For camber changes, one shim added or removed from both bolts changes camber (plus or minus) ⅓°.

After obtaining the proper setting, tighten the shaft-to-bracket nuts and recheck camber and caster. Then torque the nuts to 60-75 ft lbs on Series 10, 85-100 ft lbs on Series 20 and 120-155 ft lbs on Series 30 and 40. These torques should be rechecked at the end of the first 1000 miles of driving when these adjustments are made.

50 to 80 Series

Caster adjustments are made by changing the location of the lower control arm shafts with reference to the notched plates welded to the crossmember. Camber adjustments are made by means of shims between the upper control arm brackets and the frame.

For caster adjustment, check to determine the amount of change required. Then mark the location of the control arm shaft with reference to the notched attaching plate. Loosen the shaft-to-crossmember bolts to free the shaft from the notches in the attaching plates. Move shaft rearward to decrease caster or forward to increase caster. Moving shaft one notch changes caster approximately ½°.

For camber adjustment, determine the amount of change required. Then remove two upper nuts and bolts attaching control arm bracket to frame and loosen two lower bolts. Raise vehicle at the crossmember until control arm bracket can be pried away form support. Insert or remove shim at both bolts equally as required. The addition of a shim at both bolts increases camber about ½°.

COIL SPRING SUSPENSION

1963

This suspension, Fig. 3, consists of upper and lower control arms pivoting on steel threaded bushings on upper and lower arm shafts which are bolted to the front suspension crossmember and bracket assembly. These control arms are connected to the steering knuckle through pivoting ball joints. A coil spring is located between the lower con-

Fig. 3 Coil spring suspension. 1963

trol arm and a formed seat in the suspension crossmember, thus the lower control arm is the load-carrying member. The double-acting shock absorbers are also attached to the lower control arms and connect with the frame to the rear of the suspension on the upper end.

Coil Spring, Replace

1. Raise vehicle and support on frame to allow control arm to swing free.
2. Disconnect shock absorber at lower end (also stabilizer on P10 model).
3. Loosen lower ball stud nut. Back up steering knuckle boss and rap sharply with hammer to loosen ball stud.
4. Place tool shown in Fig. 4 across top of fifth coil.
5. Compress spring enough to clear spring tower, then remove lower ball stud nut.
6. Disconnect lower ball stud from knuckle and swing lower control arm free. Immediately release spring by backing off compressor, and withdraw spring.
7. Reverse removal procedure to install spring.

Ball Joint Inspection

Upper Ball Joint

1. Raise vehicle and support on frame to allow control arms to hang free.
2. Remove wheel assembly.
3. Support lower control arm with adjustable jackstand and disconnect upper ball stud from steering knuckle.
4. Reinstall nut on ball stud and measure torque required to rotate stud with torque wrench. If torque is not within 5 to 10 ft-lbs, replace ball joint.

Lower ball joints are a loose fit when not connected to the steering knuckle. Wear may be checked without disassembling the ball stud as follows:

Lower Ball Joint

1. Support weight of control arms at wheel hub and drum.
2. Measure distance between tip of ball stud and tip of grease fitting below ball joint, Fig. 5.
3. Move support to control arm to allow wheel hub and drum to hang free. Measure distance as indicated in Step 2. If the distance in measurements exceeds .060" ($\frac{1}{16}$") ball joint is worn and should be replaced.

Fig. 5 Checking lower ball joint for wear. 1963

Fig. 4 Removing or installing front coil spring. 1963

TORSION BAR SUSPENSION

1960-62

All trucks *except Forward Control models* have independent torsion bar front suspension with ball joints connecting each steering knuckle to a set of upper and lower control arms. Two basic suspensions which are adapted for various load ratings are used; one for Series 10, 20, 30 and 40 trucks and one for Series 50, 60, 70 and 80. The suspensions, Fig. 6, include the frame front crossmember, control arms and shafts, ball joints, torsion bars, steering knuckles and attaching parts.

Fig. 6 Torsion bar front suspension. 1960-62

10 Through 40 Series

The front end of each torsion bar is supported in a steel tube in the lower control arm and firmly held in position in the hexagon section of the tube. The rear of the torsion bar is supported in an adjustable anchor connected to a special crossmember. The upper end of each shock absorber is bolted to a frame bracket and the lower end is bolted to the lower control arm.

50 Through 80 Series

The front end of each torsion bar is supported in the upper control arm and firmly held in the hexagon section of the arm. The rear of the torsion bar is supported in a bracket attached to the outside of the frame side rail and firmly held by the hexagon portion of the bracket. The bar is located and locked in the bracket by a pin which passes through a hole in the bracket and a notch in the torsion bar rear hex.

Torsion Bars

Torsion bars are furnished as right and left hand parts and must be installed on correct side of vehicle so proper vehicle height can be obtained. New bars may be identified by colored bands located about 6″ from rear hex. One band indicates right hand bar and two bands indicates left hand bar. *Use caution in handling torsion bars to prevent nicks or scratches. If bars are nicked or scratched, stress concentrations and corrosion can lead to failure of the bar in operation.*

1960 Series 10 to 40

To remove a torsion bar, remove upper control arm bumper from control arm and disconnect shock absorber. Raise vehicle and support frame so control arms are at full rebound position. Back off adjusting bolt to unwind the torsion bar, Fig. 7, until bolt and lower spacer can be slipped out of anchor arm. Then pull anchor arm rearward off bar.

When installing the bar, the spacer and nut must be positioned so rocker groove of spacer and ridge of nut (long sides) are parallel to crossmember. Position the arm to the bar so the rear face of the arm is flush with the rear end of the bar within (plus or minus) $\frac{3}{32}$″ to prevent failure of the bar due to stress risers developed if front corners of hex on arm rides on ridges of hex on bar.

Check the position of the spacer and nut to be sure the rocker surfaces are parallel with the crossmember. Then tighten torsion bar adjusting bolt on each side until vehicle assumes nominal curb height.

1960-62 Series 50 to 80

1. Remove rebound bumper and remove shock absorber bolt from lower ball stud support.
2. Remove weight from suspension by jacking frame until upper control arm contacts crossmember.
3. Drive lock pin out of torsion bar rear bracket.
4. Pull torsion bar to rear and out of control arm hex and bracket hex.
5. Pull torsion bar out through rear bracket. *On short wheelbase models or other models with special equipment which limits clearance for rearward removal of torsion bar, the bar may be removed in either of the following ways:*
   a. Pull bar forward to remove rear hex from rear bracket. Loosen

Fig. 7 Unloading torsion bar. 1960-62 Series 10 to 40

Fig. 8 Installing torsion bar lock pin. 1960-62 Series 50 to 80

Fig. 9 Torsion bar anchor bolt. 1961-62 Series 10 thru 40

upper control arm bracket nuts. Pull control arm out far enough so torsion bar can clear outside of rear bracket. Then pull torsion bar rearward to remove front hex from control arm. Tilt bar and remove through wheel opening.

b. Pull bar to rear to remove front hex from upper control arm. Remove upper control arm bracket bolts. Swing control arm rearward around ball joint. Then pull torsion bar forward to remove rear hex from rear bracket. Tilt bar downward and out forward end of vehicle.

6. Reverse removal procedure to install the torsion bar. Drive lock pin into bracket flush with surface, Fig. 8.

1961-62 Series 10 to 40

The torsion bar remains practically the same as 1960 except that the locating dimple in the front socket has been removed, thus changing the installation procedure as follows:

1. Prior to installation of rebound bumper, and with front suspension in full rebound position, install front hex of torsion bar into lower control arm socket and slide forward to position rear of bar at center of crossmember.
2. Locate upper spacer and nut, Fig. 9, on top of crossmember. Install special washer and lower spacer on bolt, insert bolt up through crossmember and upper spacer and start into nut. *Spacer and nut must be positioned so rocker groove of spacer and ridge of nut are parallel to crossmember, with locating lug on lower spacer inboard.*
3. Assemble torsion bar arm to hex of torsion bar so spacer and bolt can be slipped into arm when bolt engages about half the threads of nut. Position arm to bar so rear face of arm is flush with rear end of bar within (plus or minus) $\frac{3}{32}$".
4. Check position of spacer and nut to be sure lower spacer locating lug is inboard, then tighten torsion bar adjusting bolt on each side until vehicle assumes normal curb height.
5. Install rebound bumper.

Control Arms & Ball Joints

The ball joint on the control arm which *does not* carry the torsion bar is checked for wear by checking the torque required to rotate the ball stud in the assembly as follows:

1. Support frame and separate torsion bar from control arm.
2. Loosen ball joint stud nut. Release stud by rapping sides of steering knuckle at flats adjacent to stud. Then remove nut, separate stud from knuckle and remove rubber seal.
3. Install nut on stud and measure torque required to turn stud. Torque should be at least 2 ft lbs on Series 10 to 40, and 5 ft lbs on Series 50 to 80.
4. If excessive wear is indicated on this joint, both upper and lower joints should be replaced. If a tight joint is suspected, maximum allowable torque, with joint well lubricated, should be 15 ft lbs on Series 10 to 40, and 20 ft lbs on Series 50 to 80.

If inspection of ball joint as outlined above indicates that joint is satisfactory, inspect the joint on the control arm which *does* carry the torsion bar as follows:

1. With ball joints, control arms and steering knuckles completely installed, support vehicle weight on wheels or wheel hubs.
2. Using outside micrometer or caliper, measure distance between end of lube fitting and end of ball stud and record the dimension. Repeat at ball joint at opposite side of vehicle.
3. On series 10 to 40, support vehicle weight at outer end of each lower control arm so wheels or wheel hubs are free. On Series 50 to 80, support vehicle at center of crossmember to let wheels hang.
4. If the difference in dimensions on either side is greater than $\frac{3}{32}$", the joint is excessively worn and the joint at both sides of the vehicle should be replaced.
5. If the above measurements do not indicate any reason for ball joint replacement, test the torque tightness of the stud nut at each side of the vehicle as follows:
   a. Examine for evidence of looseness of stud in knuckle.
   b. If no evidence of looseness, remove cotter pin and, with prick punch or equivalent, mark nut and stud to identify relative location.
   c. Back off stud nut. Then retighten to original position and observe torque reading. If less than 45 ft lbs, stud may have been loose in steering knuckle and replacement of joint is recommended.

STEERING GEAR

The steering gear, Figs. 10 and 11, is the recirculating ball type. The principal working arrangement consists of a "ball nut" connected to the steering worm and in mesh with the sector gear. Precision finished helical grooves inside the ball nut match helical grooves in the worm, and it is in these grooves that ball bearings roll around as the steering wheel is turned.

There are two complete ball circuits within the ball nut. To keep the balls from running out of the end of either circuit, the nut is equipped with two tubular ball guides, each of which deflects the balls away from their helical path at one end of their travel, guides them diagonally across the back of the nut and returns them to their helical path between the ball nut and the worm at the other end of their travel.

The balls constitute a thread between the worm and ball nut so that when the worm is turned, the nut moves along the worm as with an ordinary screw thread.

STEERING GEAR ADJUSTMENTS

There are only two adjustments to be made on this gear and the following procedure must be made step-by-step in the order given.

1. Disconnect drag link from pitman arm.
2. Loosen the sector shaft lock nut and turn the adjusting screw a few turns counter-clockwise. This removes from the worm bearings the load imposed by close meshing of rack and sector teeth. Turn steering gear gently in one direction until stopped by gear, then turn it back one turn.
3. With a spring scale, measure the

pull at the rim of the wheel which is required to keep the wheel in motion. This should be between ½ to ¾ lbs on light duty gears and 1½ to 2 lbs on heavy duty gears. If the pull necessary to move the wheel does not lie between these limits, adjustment of worm bearings is necessary.

4. To adjust worm bearings, loosen the worm shaft lock nut and turn the worm bearing thrust screw, until there is no perceptible end play in worm. Check pull at wheel rim, readjusting if necessary to obtain proper pull. Tighten lock nut and recheck pull after lock nut is tightened.
5. After proper adjustment of worm is obtained and all mounting bolts securely tightened, adjust cross shaft lash adjuster as follows:
6. First turn steering wheel gently from one stop to the other, carefully counting total number of turns. Then turn wheel back half way to center position. Mark wheel at top or bottom center with a piece of tape.
7. Turn lash adjuster clockwise to take out all lash in gear teeth and tighten lock nut.
8. Check pull at wheel rim with spring scale as before, taking highest reading on scale as wheel is turned through center position. This should be between ⅞ to 1½ lbs on light duty models and 2¾ to 3¼ lbs on heavy duty gears.
9. Readjust if necessary to obtain proper pull. Tighten lock nut and recheck pull as it must lie between 2 and 2½ lbs. after lock nut is tightened.
10. Connect drag link to pitman arm.

STEERING GEAR, REPLACE

1963

1. Loosen bolt attaching lower end of shaft to steering gear.
2. Disconnect pitman arm from gear.
3. Unfasten steering gear from frame and remove from vehicle.

1960-62

1. Loosen bolt attaching lower end of intermediate shaft to steering gear.
2. Use a suitable puller to remove the pitman arm from the steering gear.
3. Remove all steering gear-to-frame mounting bolts and remove gear from vehicle.
4. To install, first be sure that steering wheel is in straight ahead position and that the steering gear is centered. With the gear in centered, the mark on the worm shaft will be in the 12 o'clock position on Series 10 to 40, and in the 9 o'clock position on Series 50 to 80.
5. Position steering gear in place on frame. At the same time slide the worm shaft into the flexible or universal coupling. Check that the mark on the intermediate shaft lines up with the mark on the steering gear worm shaft.
6. Tighten mounting bolts and bolt at coupling or universal joint.

1952-59 Conventional

1. Disconnect horn wire and remove wire retainer from steering mast jacket.
2. Remove horn button and steering wheel.
3. Remove seat cushion except on Forward Control models.
4. Unfasten mast jacket from instrument panel.
5. On ½ and ¾ ton, disconnect gear shift upper control shaft support from mast jacket. Separate upper control shaft from lower shaft by removing lower bolt from shaft clamp.
6. Unfasten and slide toe board grommet and seal up on mast jacket and remove toe board plate.
7. On Forward Control models, hoist front end of vehicle and remove mast jacket opening cover located underneath vehicle.
8. On ½ and ¾ ton, unfasten gearshift control housing from mast jacket.
9. Unfasten gear housing from frame.
10. On Forward Control models, gear can now be moved forward, down and out of vehicle.
11. On all other models, unfasten and move left fender skirt out of the way.
12. Slide steering gear slightly upward toward toe board, then rotate until attaching flange is up. Raise slightly and lift gear out over fender.
13. Reverse the foregoing procedure to install the gear.

1952-59 Cab-Over-Engine

1. Remove steering wheel and disconnect dash mounting bracket.
2. Remove left hand floor pan and steering column grommet.
3. Disconnect horn wire.
4. Remove signal switch bowl.
5. Remove fender skirt.
6. Remove pitman arm.
7. Unfasten gear from frame.
8. Move gear back to clear radiator grille. Then drop gear down through fender skirt opening, pulling steering column through opening in floor.
9. Reverse above procedure to install gear.

When checking fluid level, be sure that bubbles are not present in the fluid. If bubbles are found, bleed the system as outlined further on.

Another cause of noise in the pump can be a sticky valve which will produce a buzzing sound. This can be determined by checking for excessive pump pressure.

Obstructions in the hydraulic system will also cause a noise. For instance, a slight burr on the edge of one of the valve spool lands or a hose restriction will cause a noise on turns. Removal of the burr with a fine stone or replacement of the hose will correct the condition.

If belt noise, possibly accompanied by a knock or steering wheel oscillation, is present on extreme turns, it is reasonable to assume that improper pump belt tension is the cause.

POWER STEERING

The power steering, Fig. 12, combines the standard recirculating ball type steering gear with hydraulic booster equipment. The 1960-63 system has the control valve located directly on the steering gear, thus simplifying power line arrangement and improving steering response. Earlier models had the control valve incorporated with the steering

Fig. 12 The 1960-63 power steering gear and control valve. Earlier models use the standard steering gear with a separate control valve

linkage. The power cylinder, on all models, is also incorporated in the steering linkage.

Checking for Leaks

If an oil loss is indicated in the power steering system, first wipe all units dry. This includes the pump, hoses, power cylinder and control valve. Then fill the reservoir, start the engine, operate the steering gear and observe where the leak occurs.

A possible place for leakage would be at the pump, involving either the reservoir-to-pump body seal or the pump drive shaft oil seal. In the case of pump leakage the repair is fairly simple requiring very little time to replace the seals. Other leaks may require the removal of the unit from the vehicle and more involved service.

Improperly installed seals is a major cause of leaks. Damage to "O" ring seals will cause leaks if the housings have sharp edges which cut the "O" rings. Sharp edges should be removed with a fine stone and new seals installed.

Checking Noise

To determine whether or not the steering unit is at fault, disconnect the pump drive belt and operate the vehicle. If the noise is no longer present the steering gear is eliminated and the next check should be the power unit.

It is well to bear in mind that a power steering complaint should not be diagnosed without first checking fluid level and drive belt tension. Either may cause noises and malfunctions which could conceivably be blamed on the steering unit.

Hard Steering

Dirt in the system has been found to be a cause of hard steering as greater effort is required to reposition the spool and bring the power steering into operation. The repair will be a complete cleaning of the hydraulic system. A pump relief valve stuck in the open position can be the cause of hard steering as there will be zero pump pressure.

Fluid Level

Turn wheels to full left turn position before checking fluid level. Fill reservoir to within ½" to 1" of top of reservoir. If the reservoir is full at a position other than full left turn, the reservoir will overflow through the vent during turn operations.

Bleeding Hydraulic System

After a pump or control valve has been installed or a disconnected oil line has been reconnected, the air that entered the hydraulic system must be bled out, otherwise noisy and unsatisfactory operation will result.

1. Fill the reservoir to the proper level and let oil remain undisturbed for about two minutes.
2. Raise front end of vehicle so wheels are free.
3. Start engine and run at idle for two minutes.
4. Turn wheels right and left, lightly contacting the stops.
5. Lower vehicle and turn wheels right and left on the ground.
6. Recheck for leaks.
7. Recheck oil level and refill as required.

Pump Belt Tension

1. Loosen pump-to-mounting bracket attaching screws.
2. With a suitable tool, pull pump outward until tension on belt is such that a 15 lb load applied midway between the pump pulley and fan pulley will result in a ½ to ¾" deflection of the pump belt.
3. Tighten attaching screws.

Checking Pump Pressure

1. Disconnect pressure line at oil pump and attach a 1000 psi pressure gauge.
2. With engine warm and idling, open the gauge valve. Turn wheels (on ground) against stops. Pressure should not be less than 900 psi.
3. If less than 900 psi, slowly close valve while observing gauge. If pump is OK, pressure will increase. *Do not leave valve closed for more than 15 seconds.*
4. If pressure does not increase when valve is closed, the pump must be removed for service.
5. If pump is OK, remove gauge and reconnect hose. Then bleed the system of air as outlined above.

CONTROL VALVE, 1960-63

Removal

1. Disconnect steering shaft from lower coupling.
2. Remove hoses from valve.
3. Remove pitman arm.
4. Unfasten and remove steering gear.
5. Remove adjuster plug.
6. Remove control valve from gear by grasping stub shaft and pulling out.

Disassembly

NOTE—It is very uncommon to have to make any service repairs to the valve assembly, with the possible exception of replacing the valve spool dampener O-ring. Do not disassemble the valve unless absolutely necessary since this may result in a damaged assembly. If the valve spool dampener O-ring requires replacement, remove the valve spool only. Replace the O-ring and reinstall the spool immediately. Do not disassemble further.

1. Remove spool spring by prying on small coil, using a small screwdriver. *Do not pry against valve body as this may result in a sticky valve.* Work spring onto bearing diameter of the stub shaft. Slide spring off stub shaft.
2. Remove valve spool with extreme care. *The diametral clearance between valve body and spool may be as low as .0004". The slightest cocking of the spool may jam it in the valve body. To remove the spool, hold the valve assembly in both hands with the stub shaft pointing downward. Push lightly on the valve spool with a pencil or small brass rod by inserting it through the openings in the valve cap until the spool is far enough out of the valve so that it may be grasped by the hand, Fig. 13. Withdraw the spool with a steady oscillating pull to prevent jamming, Fig. 14. If slight sticking occurs, make a gentle attempt to reverse the withdrawal procedure. If this does not free the spool, it has become cocked in the valve body bore. Do not attempt to force the spool in or out if this occurs. Rather, continue to disassemble the valve and return to the spool as described later.*
3. Remove stub shaft, torsion bar, and valve cap by holding valve assembly in both hands as before only with thumbs on the valve body. Tap torsion bar lightly against workbench. This will dislodge the cap from the valve body-to-cap pin. The stub shaft and valve cap assembly can

Fig. 13 Separating valve spool from valve body. 1960-63

now be removed from the valve body.

4. If the valve spool has become cocked as in Step 2, it can now be freed. By visual inspection on a flat surface, it can be determined in which direction the spool is cocked. A very few light taps with a soft-faced mallet may align the spool in the bore and free it. *Do not tap the spool with anything metallic. If spool can be rotated, it can be removed.*
5. Remove O-ring dampener seal from spool and discard.
6. Carefully cut valve rings and ring back-up seals. Remove and discard, providing the rings show evidence of excessive wear.

Inspection

1. If valve leaks externally around torsion bar, the entire valve assembly should be replaced.
2. Check the pin in the valve body which engages the cap. If it is badly worn, cracked or broken, the entire valve assembly should be replaced.
3. Check the worm pin groove in the valve body (smaller of two). If worn badly, the valve assembly should be replaced.
4. Check the spool drive pin in the stub shaft. If badly worn, the valve assembly should be replaced.

Fig. 15 Installing valve body rings. 1960-63

5. Examine the spool O.D. for nicks, burrs or excessive wear areas. If any are found the valve assembly should be replaced. A slight polish is normal on the valve surfaces.
6. Examine the valve body for nicks, burrs or bad wear spots. If any are found, replace the valve assembly. As on the spool, a slight polish is normal on the valving surfaces.
7. Check the fit of the spool in the valve body without the spool dampener O-ring seal. The spool should rotate smoothly without binding or catching. If either occurs, the valve assembly should be replaced. A small burr on the spool or in the valve body can usually be removed by use of a very fine hone.
8. Measure the length of the spool spring. The free length should be approximately .79″. If it measures .76″ or less, the spring should be replaced as it has taken a permanent set.

Reassembly

NOTE—As valve is being assembled, lubricate parts with Automatic Transmission fluid.

1. Assemble four valve ring and four back-up O-ring seals on ring grooves on valve body. Do not allow seals to become twisted. Assemble valve rings in ring grooves over O-ring seals by carefully slipping rings over valve body, Fig. 15. The rings may appear loose or twisted in the grooves but the heat of the oil during operation will cause them to straighten.
2. Install new valve spool dampener O-ring seal in valve spool groove. Do not allow seal to twist in groove.
3. Assemble stub shaft in valve body by aligning groove in valve cap with pin in valve body, Fig. 16. Tap lightly on cap with soft-faced mallet until cap is against shoulder in valve body with valve body pin in cap groove. *Make sure groove and pin are in line before tapping on cap. Hold these parts together during rest of assembly.*
4. Slide valve spool over stub shaft with notch toward valve body. Align notch with spool drive pin in stub shaft and carefully engage spool in valve body bore. *Because the clearance between the spool and valve body is very small, extreme care must be taken when assembling these parts. Push the spool evenly and slowly with a slight oscillating motion until the spool reaches the drive pin. Rotate the spool slowly with pressure until notch engages the pin. Before pushing the spool in completely, make sure the dampener O-ring is evenly distributed in the spool groove. Slowly push spool in completely, with extreme care taken not to cut or pinch the O-ring seal.*
5. Slide spool spring over seal protector and work spring down until it is seated in undercut part of stub shaft. Take care not to scratch or mar the sealing surfaces of the stub shaft.
6. If during assembly of the valve the stub shaft and cap assembly is allowed to slip out of engagement with the valve body pin, the spool will be permitted to enter the valve

Fig. 14 Removing valve spool. 1960-63

body too far. The dampener O-ring seal will expand into the valve body oil grooves, preventing withdrawal of the spool. Attempt to withdraw the spool with a light pull and much rotary motion. If this does not free the spool after several tries, make sure spool is free to rotate. Place valve body on flat surface (notched end up) and tap spool with a wooden or plastic rod until the O-ring seal is cut and the spool can be removed. Replace the dampener O-ring seal and proceed with assembly as before.

Installation

1. Align valve body drive pin on worm with the narrow pin slot on the valve body.
2. Insert valve in valve housing. *Do not push against stub shaft as it may cause stub shaft and cap to push out of valve body, allowing spool seal to slip in valve body oil grooves as already described. The valve should be pushed in by pressing against the valve body with the finger tips. Be sure the valve is properly seated before adjusting the adjuster plug. The return port in the valve housing should be fully visible at this time, Fig. 17.*
3. Install adjuster plug assembly. Check valve assembly drag with an

Fig. 16 Assembling stub shaft, torsion bar and cap in valve body. 1960-63

Fig. 17 Control valve properly installed in housing. 1960-63

Fig. 18 Adjusting adjuster plug. 1960-63

inch-pound torque wrench. Then adjust the adjuster plug, Fig. 18, until the preload is 1 to 3 inch lbs in excess of valve assembly drag.

CONTROL VALVE, 1955-59

Remove and Replace

1. Disconnect hydraulic lines from the valve and drain hoses.
2. Remove link-to-steering knuckle third arm nut and ball stud-to-pitman arm nut.
3. Disengage ball stud from pitman arm by tapping on lower end of arm to squeeze tapered ball stud from hole in pitman arm. *Do not pry ball stud from pitman arm as this would deform the sleeves and jam the valve.*
4. Reverse the removal procedure to install the valve and bleed the system of all air as outlined previously.

Disassemble and Inspect

1. Disassemble as suggested by Fig. 19. *Special care should be exercised to protect the spool edges and the bore of the valve housing from damage.*
2. Inspect all parts for scratches, burrs, distortion, and evidence of wear.
3. Replace all seals, gaskets and covers.

Reassemble

1. Referring to Fig. 19, assemble spool into valve housing. On L.C.F. models, install spool with small diameter next to sliding sleeve end. On conventional models, install spool with large diameter end next to sliding sleeve end.
2. Assemble large and small bore "U" cup seals over large and small projection ends of spool with lips of seals facing each other.
3. Assemble bushing plates on their respective ends of spool.
4. Insert spool bolt through screw stop and assemble spacer on bolt.
5. Assemble lock pin in hole of screw stop and through slot in bolt head to secure bolt to screw stop.
6. Place inner sleeve in outer sleeve and flange. Then assemble ball seat, ball stud, ball seat, spring, spring seat in sliding sleeve.
7. Assemble screw stop with bolt to sleeve assembly by threading screw stop into inner sleeve and tighten securely.
8. Assemble bushing plate over bolt and on shoulder of outer sleeve flange.
9. Insert spool bolt through hole in spool and assemble lock nut. Draw up nut tight and back off less than ¼ turn until spool can be rotated with a minimum of end play.
10. Position drag link flange on valve housing so that ball stud is on side opposite valve ports. Align holes and assemble three bolts and tighten securely.
11. Place valve in vise and check ball stud travel by pushing on stud. Stud should have ⅛" travel along drag link axis. This travel is necessary to allow valve to open all the way.

Fig. 19 Control valve. 1955-59

POWER CYLINDER, 1960-63

Removal

1. Remove hydraulic lines from cylinder.
2. Remove cotter pin and loosen adjuster screw securing end of cylinder to front bracket enough to permit cylinder to be removed.
3. Repeat procedure to remove opposite end of cylinder from rod bracket.
4. Loosen clamp bolt and unscrew ball socket connection from push rod end of cylinder.

Repairs

The only repair to be made to the power cylinder in the field is the replacement of the seal parts. With cylinder disassembled, assemble the seal parts as follows:

1. Assemble open side of "U" cup seal over rod and into the bearing cavity, guide assembly, dust seal (wide side away from seal cavity), and wiper assembly.
2. Slide parts in place on rod and lock in place with snap ring.

Installation

1. With tie rod ball stud in place in socket, screw plug in tight, then back off to nearest hole before installing cotter pin.
2. Turn steering wheel from stop to stop and check that the cylinder does not bottom and prevent stops from hitting axle.
3. Connect and tighten hydraulic hoses. Make certain hoses are not kinked and will not bind when vehicle is turned.
4. Check for leaks and bleed system as outlined previously.

POWER CYLINDER, 1955-59

Removal

1. Remove hydraulic lines from cylinder.
2. Remove bolt securing end of cylinder to front bracket.
3. Remove U-clamps attaching opposite end of cylinder to tie rod.

Repairs

The only repairs to the power cylinder to be made in the field is the replacement of the seal parts. With the power cylinder disassembled as suggested by Fig. 20, reassemble as follows:

1. Assemble open side of "U" cup seal over rod and into bearing cavity, seal back-up washer, dust seal (with

Fig. 21 Power steering pump. 1960-63

side away from seal cavity), and scraper washer.

2. Slide parts in place on rod and lock in place with snap ring.

Installation

1. Install U-clamps on tie rod and through bracket on end of power cylinder.
2. The distance from the centerline of the furthest outboard U-clamp to the centerline of the ball stud on the opposite side should be:

Series	Distance
3100, 3200	18⅞″
3600, 3800	19¾″
4000	21¾″
5000 (1955-57)	22¼″
5000 (1958-59)	① 21½″
5000 (1958-59)	② 14 27/32″
6000	21¾″
7 to 10000 (1955-57)	13⅜″
7 to 10000 (1958-59)	13⅛″

① With two attaching bolts.
② With three attaching bolts.

3. After adjusting to proper distance, turn steering wheel from stop to stop and check that cylinder does not bottom and prevent stops from hitting axle.
4. Attach opposite end to axle bracket, connect hoses, check for leaks and bleed system.

POWER PUMP, 1960-63

1. Disassemble the pump as suggested by Fig. 21.
2. To assemble, insert shaft into housing, being sure shaft seats by pressing with thumb on splined end.
3. Install thrust plate on dowel pins with ported face to rear of pump housing.
4. Install pump ring on dowel pins with direction of rotation arrow to rear of pump housing. *Arrow on outer edge of pump ring points in direction of rotation.*
5. Install rotor over splined end of pump shaft and install snap ring. *Assemble rotor with countersunk side toward shaft.*
6. Install vanes in rotor slots with radius edge toward outside, Fig. 22.
7. Lubricate outside diameter and chamfer of pressure plate with vaseline to insure against damaging O-ring and install on dowel pins with ported face toward pump ring. Using a 2¾″ diameter tube to apply pressure to outer edge only, seat pressure plate with use of an arbor press. *Never press or hammer on center of pressure plate as this will cause permanent distortion with resulting pump failure.*
8. Install pressure plate springs, one over each dowel pin.
9. Lubricate outside diameter and chamfer of end plate with vaseline to insure against damaging O-ring and install in housing using an arbor press.

Fig. 22 Proper valve installation. 1960-63 pump

10. Install end plate retaining ring while pump is in arbor press. Be sure it is completely seated in groove of housing.
11. Install flow control spring.
12. Install flow control plunger, being sure hex head screw goes into bore first.
13. Install reservoir, studs, seals, union, union seal and drive shaft key. Support shaft on opposite side of key when installing key.
14. Install pump on vehicle and bleed system of air.

POWER PUMP, 1958-59

1. Disassemble pump as suggested by Fig. 23.
2. To assemble the pump, install new discharge union seal and assemble discharge union to lower end of pump cover. Tighten to 10-20 ft lbs.
3. Lubricate shaft seal and end of a pusher tool. Then press seal into seal cavity of pump body until tool bottoms. *Seal should be installed with part numbers on metal face of seal toward outside of pump.*
4. Install dowel pins to pump body, Fig. 24.
5. Install new O-ring to pump body groove.
6. Install Woodruff Key to shaft.
7. Install shaft and key to pump body, being careful not to damage shaft seal.

Fig. 20 Power cylinder. 1955-59

Fig. 23 Power steering pump. 1958-59

8. Install pump ring to dowel pins, with arrow on outside of pump ring pointing as shown in Fig. 25.
9. Install rotor over splined end of drive shaft. Rotor must be assembled with side having countersunk end of splines toward pump body. Install retainer ring to groove at end of drive shaft, Fig. 25.
10. Assemble vanes to rotor, Fig. 25.
11. Install pressure plate to dowel pins and pump ring. The ½" bore in center of plate must locate over drive shaft.
12. Install O-ring in counterbore of pump cover.
13. Install spring and pressure relief valve to cover and install cover to pump body, pump ring and pressure plate. *Capscrew end of valve should be inserted into cover bore first.*
14. Install cover-to-body attaching bolts and tighten alternately to 25-30 ft lbs. Note that the two long bolts are installed at top of pump.
15. Install new gaskets on pump body and cover.
16. Position reservoir over gaskets on pump and install spring over inlet line tube inside reservoir. Then position manifold over attaching bolt holes on bottom of reservoir. Install bolts and torque to 8-10 ft lbs.
17. Place spring and filter retainer on end of spring and over reservoir inlet tube. Compress spring and retainer and slip filter into place over tube. Release spring and seat filter in shallow depression in manifold. *Do not install reservoir cover until pump is installed on car and filled*

Fig. 24 View of pump body with shaft and rotor. 1958-59

Fig. 26 Power steering pump. 1955-57

Fig. 25 Pump ring and rotor installed. 1958-59

with fluid. Then install new gasket and torque cover bolt to 7-9 ft lbs.

18. Install pump on vehicle and bleed system of air.

POWER PUMP, 1955-57

1. Disassemble pump as suggested by Fig. 26.
2. To assemble, apply Lubriplate and install new O-rings in pump cover, on cam ring, and in pump body.
3. Install rotor and vanes on pump body with beveled edge of vanes against cam ring inner diameter.
4. Install alignment sleeve in cam ring and install cam ring on pump body. *The wider edge of cam ring is correct side to pump body. Be certain to align bolt holes in cam ring with bolt holes in pump body. The rotor should be installed with the rounded side of the splines toward the generator end of the pump.*
5. Install pressure plate in pump cover.
6. Install filter retainer and filter on pump cover.
7. Install pump cover to pump body with three bolts.
8. Install plunger and flow spring in pump cover.
9. Install plug and O-ring, cover plate and retainer spring.
10. Install oil filter retainer spring in pump cover.
11. Install reservoir with two bolts and two sealing washers. *The brass fitting seats are of the pressed-in type and are replaceable in the event of a fitting leak. Tap threads in the hole of the seat and then pull the seat by using a bolt threaded into the tapped out seat and a flat washer and nut as an extractor.*
12. When installing new seats, align the seat in its bore and press it into place, using the correct hose or tube fitting as a pressing tool.
13. Install pump on vehicle and bleed system of air.

Power Train Section

POWER TRAIN, REPLACE

The preferred method of removal and installation described below utilizes a special Power Train Cradle (J-7894), Fig. 1, mounted on a transmission jack with the car on a hoist. Equipment limitations may require a modified approach to this operation but certain precautions must be observed.

1. The complete power train should be supported only at the engine pan rail. Under no circumstances should it be supported on the pan itself.
2. No jacking fixture or floor support should be used unless it is capable of supporting the weight of the power train (approximately 460 lbs.).
3. The center of gravity or balance point of the power train is located approximately .200" behind the front face of the cylinder block.
4. No jack should be used that does not permit the power train to be lowered *gradually*. This is essential to avoid damage to components when close clearances are encountered during removal.

Fig. 1 Power train cradle (J-7894)

Power Train Removal

1. Remove engine access cover from vehicle floor.
2. Remove carburetor air cleaners.
3. Disconnect return air hose from air heater (if equipped).
4. Remove engine-to-body front seal retainer.
5. Disconnect carburetor linkage and electrical connections as required.
6. Remove engine rear grille and skid plate, then remove retainers from rear and side engine seals.
7. Disconnect parking brake return spring from engine mount front crossmember.
8. Pull choke cable forward until it clears engine front mount (1961).
9. Disconnect accelerator control rods at transmission idler lever and push lever-to-carburetor rod up into engine compartment.
10. Disconnect and plug fuel lines to prevent leakage.
11. Disconnect speedometer cable at differential carrier.
12. If equipped with air heater, disconnect flexible hoses at engine. If

Fig. 2 Dial indicator and support mounted on transmission

equipped with gasoline heater, disconnect heater fuel line.

13. Pull U-joints from differential carrier by removing axle shafts.
14. On manual transmission jobs, disconnect clutch linkage as required. Disconnect shift tube coupling at transmission. Loosen coupling clamp and push coupling into tube until it clears engine front mount.
15. If equipped with automatic transmission, disconnect oil cooler. Also shift tube cable and grommet plate at rear of control tunnel. Remove cable from transmission by rotating throttle valve lever its full limit counterclockwise and withdraw cable from case. Place receptacle for transmission oil beneath transmission and remove oil filler tube.
16. Position hydraulic jack stand under engine, using Power Train Cradle, Fig. 1.
17. Remove two nuts from front engine mount (at transmission) and nut from front engine mount. *If front engine mounting bracket and shims are removed from transmission, the same amount of shims must be replaced. Rear wheel toe-in will be affected if shims are altered.*
18. Lower power train gradually and watch for possible interference at rear mounting and left rear lower control arm.
19. Remove exhaust pipe and muffler.

Power Train Installation

Reverse the removal procedure to install the power train. Be sure all harness wires, fuel lines and levers are out of the way prior to installation of the power train to prevent damage.

SEPARATION OF POWER TRAIN COMPONENTS

Remove Transaxle From Engine

1. With power train removed, support transaxle with chain hoist or other suitable lift and a sling.
2. Drain transmission and differential carrier.
3. Remove starting motor.
4. Remove two screws securing clutch pull rod dust seal; then remove pin attaching pull rod to clutch fork.
5. Remove bolts securing differential carrier to clutch housing. Pull transaxle away horizontally to prevent damaging clutch shaft, using care not to damage clutch fork. Remove clutch shaft.
6. To complete operation, remove clutch fork and clutch release bearing from differential carrier. The fork is attached to the carrier by a ball socket and spring retainer which is easily slipped off to allow the release bearing to be slipped off its shaft in the carrier.
7. Separate transmission from differential carrier.

Assemble Transaxle To Engine

1. Couple transmission to differential carrier, using new gasket. Be sure to engage splines of transmission mainshaft to internal splines of pinion in differential carrier. Install four bolts and torque them to 24-32 ft. lbs.
2. Install clutch release bearing and clutch fork on differential carrier. The bearing slips over the shaft and the fork has a spring retainer and socket which attaches to ball stud on carrier.
3. Install clutch shaft in transaxle; then check distance from end of clutch release bearing shaft to end of clutch shaft. If fully engaged, dimension should be $2\frac{9}{16}''$ (plus or minus $\frac{1}{32}''$).
4. Align both holes in differential carrier and clutch housing. Pilot clutch shaft splines into the clutch; then secure differential carrier to clutch housing with bolts.
5. Connect clutch push rod to clutch fork with pin; then position and secure clutch push rod dust seal to clutch housing with two screws.
6. Install starter and fill transmission and differential carrier with lubricant to the proper level.

Remove Powerglide Transaxle From Engine

1. Disconnect short length of hose connecting vacuum modulator tube to carburetor balance tube.
2. Remove starting motor.
3. Disconnect converter from engine flex plate by removing the three attaching bolts via the access hole at the 12 o'clock position in the converter housing. The converter may be rotated by prying against the starter gear teeth on the converter housing with a screwdriver.
4. Support transaxle with chain hoist or lift and sling.
5. Unfasten differential carrier from converter housing; then pull transaxle away from engine. Remove converter and turbine shaft.

Assemble Powerglide Transaxle To Engine

1. Align converter with flex plate; then pilot converter hub into crankshaft. Align bolt holes in differential carrier and converter housing; then secure transaxle to converter housing by installing top left bolt (11 o'clock position).
2. Install flex plate-to-converter bolt (at 1 o'clock position) to prevent accidental turning of converter or flex plate and loss of attaching bolt alignment.
3. Fasten remaining converter housing-to-differential carrier bolts.
4. Install starting motor.
5. Install two remaining converter-to-flex plate bolts via access hole in converter housing. The converter can then be rotated to make the attaching points accessible by turning the converter with a screwdriver against the starter gear teeth.
6. Install engine front shield.
7. If transmission filler tube was removed from engine front shield, reinsert it through the shield at this time; then connect the vacuum modulator to the carburetor balance tube with a short length of hose.
8. Insert and secure filler tube into transmission oil pan.
9. Refill transmission with fluid.

Fig. 3 Measuring mounting difference with dial indicator and support (J-8364)

Separate Powerglide From Differential

1. With transaxle separated from engine, place transaxle on a flat surface.
2. Pull turbine shaft carefully through transmission and carrier, being careful not to damage turbine shaft bushings on pump shaft splines.
3. Remove transmission governor.
4. Unfasten transmission from carrier and pull transmission straight away from carrier to prevent pump shaft from damaging bushings in transmission and pinion shaft.
5. Remove governor gear and selective spacer from pinion shaft of differential carrier.

Selective Thrust Washer Determination

For proper operation it is necessary that sufficient end play of the Powerglide components be maintained by selection of thrust washers of various thicknesses. In the Corvair transmission, selective thrust washers are used at two locations:

1. At the front of the transmission between the front pump body and clutch drum.
2. At the rear of the transmission be-

tween the rear face of the planet carrier hub and the front face of the governor gear.

From the serviceman's standpoint, the use of the selective thrust washers at both the front and rear is a distinct advantage as final transmission end play adjustment can be made at either end of the transmission, whichever is most advantageous. *Also, there is no condition in which the selective washers would be gauged at both locations. Thus, if the repair requires axle and transmission separation, make the washer selection at the rear. Of course, if they are not to be separated, the rear thrust washer is inaccessible and the selection must be made at the front.*

Prior to reassembly of the transmission to the differential carrier after any repair which required separation of these units, the rear selective thrust washer must be determined. *Be sure low band is properly adjusted to prevent disengagement or cocking the apply linkage before tipping the transmission in its end.*

To determine the size spacer needed a dial indicator and a special support stand is available. Install the dial indicator on the support as shown in Fig. 2. Without gasket, place support J-8364 on rear pump cavity surface of transmission case so that dial indicator tip rests on planet carrier hub. Adjust indicator on J-8364 to permit maximum indicator travel and set dial at zero.

INDICATOR READING	NUMBER .016" SPACERS REQ'D	THICKNESS OF SPACERS INSTALLED
*.025—.046	None	
.047—.062	1	.016 ± .001
.063—.078	2	.032 ± .002
.079—.094	3	.048 ± .003
.095—.110	4	.064 ± .004
.111—.126	5	.080 ± .005
.127—.142	6	.096 ± .006
.143—.155	7	.112 ± .007

*If initial indicator reading is below .025", replace thrust washer at the clutch hub—front pump with .050" thrust washer, then repeat entire rear thrust spacer selection procedure.

Fig. 4 Automatic transmission rear thrust spacer usage chart

Slowly lift J-8364 and indicator off rear pump cavity and note its range of needle deflection from zero position. Properly positioned on support, indicator should not deflect more than .050" (one-half turn) when removed; otherwise raise or lower dial indicator on support post as required and again zero the gauge.

Place gauge and support on governor gear as shown in Fig. 3. Lower support slowly so that revolutions of indicator can be counted. Measurement starts once the indicator needle again reaches zero. Fully depress support on governor gear, note indicator reading and refer to Fig. 4 for spacers to be installed on governor gear. Install spacers selected at the front face of governor gear.

Assemble Powerglide to Differential

1. With new gasket in place, align carrier and transmission on a flat surface and guide pump shaft through differential carrier so as not to damage the bushing in the pinion. Then engage pinion shaft splines with planet carrier internal splines in transmission.
2. Install governor.
3. Secure transmission to carrier with four bolts. Drive the two bolts from the carrier side first and tighten to 24-32 ft. lbs.
4. Install turbine shaft, being sure to engage the two sets of shaft splines.
5. Install converter, being sure to get full engagement of splines on stator shaft, turbine shaft and front pump shaft. *Once the converter is installed, do not tip rear of transaxle downward unless some improvised converter holding plates are used to prevent converter falling off.*

Engine Section

On all service operations where threads enter aluminum, use an anti-sieze compound, such as Permatex No. 404 or its equivalent. Such service operations that can be performed with the engine in the vehicle will be so noted directly under the unit heading.

ENGINE DESCRIPTION

The engine, Fig. 5, is the horizontal opposed air cooled six-cylinder type. The cast aluminum alloy crankcase is vertically divided into two halves which are held together by bolts at the parting line. Each crankcase half has three pilot openings for individual cast iron cylinders which are positioned to the openings by means of four long studs at each cylinder. These studs pass freely through holes in the cylinder cooling fin structure and the cylinder head and serve to secure the cylinders and head to the crankcase.

The two opposing and identical aluminum cylinder heads incorporate cooling fins and built-in intake manifolds and contain wedge-shaped combustion chambers and valves for each cylinder. The valves are actuated by push rods through stamped rocker arms. Steel alloy valve seat inserts are provided for durability.

Steel tubes are used to house the push rods in the open area between the crankcase and cylinder heads adjacent to the cylinders. These tubes serve to protect the exposed push rods as well as drain back oil from the cylinder heads to a relatively shallow oil pan bolted to the bottom of the crankcase, Fig. 6.

The camshaft, which actuates the push rods through hydraulic lifters, is nested between the two halves of the crankcase below the crankshaft. This camshaft differs from the conventional design in that each of the three exhaust valve lobes are twice the width of the intake valve lobes and actuate a pair of exhaust valve lifters. The camshaft journals ride directly on the machined base metal of the crankcase. Camshaft end thrust is taken by a thrust washer located between the camshaft gear and front bearing.

No separate main bearing caps are required since the four bearings are supported entirely by the crankcase halves. The crankshaft drives the camshaft through a composition gear and drive hub. The front crankshaft seal is installed to the aluminum clutch housing (or flywheel housing) which mounts to the front of the crankcase assembly.

The engine rear housing mounts to the rear of the crankcase over four free-fitting long studs. This housing contains the oil pump, crankshaft seal and primary oil passages, Fig. 7. It provides the mounting for the distributor and the generator adapter to which the fuel pump, oil fill pipe, generator, oil filter and idler pulley are mounted.

A rectangular crankcase cover mounts to the top of the crankcase and forms a base for the centrifugal blower.

Cooling System

The engine is entirely shrouded with sheet metal pieces that attach directly to the engine and form a plenum chamber—a condition in which the pressure of the air in an enclosed space is greater than that of the outside atmosphere.

A centrifugal blower, mounted to the top of the crankcase cover, spins on a vertical shaft to deliver cooling aid outward and downward over the cylinders and heads. The air then enters a duct under each bank from where it travels rearward to be exhausted at an opening at the rear of the engine.

The rate of engine cooling is regulated by a bellows-type thermostat at the lower part of the plenum. This thermostat operates a cooling air valve which moves in and out of the eye of the blower to control the air flow. The ring closes the blower air intake until the engine has reached its correct operating temperature. In the event of a failed thermostat bellows, the ring will remain

Fig. 7 Engine lubrication

Fig. 8 Dimensions for making engine lifting adapter locally

in the open position to prevent overheating of the engine.

The blower, which runs on a sealed, permanently lubricated ball bearing, is belt-driven by a pulley mounted at the extreme rear end of the crankshaft. A generator drive pulley at the left rear of the engine and an idler pulley at the right rear provide a means of changing belt direction from a vertical plane at the crankshaft pulley to a horizontal plane at the blower pulley.

An oil cooler, through which a portion of the air passes before discharge, is mounted above the air exhaust duct near the left rear corner of the engine.

ENGINE DISASSEMBLY

Engine Removed

1. Separate differential carrier from engine.
2. Remove clutch (if equipped).
3. A difference of 1⅝" between center line of crankshaft and engine rear mounting bracket requires a special lifting adapter made locally to the dimensions shown in Fig. 8. Mount the adapter as shown in Fig. 9.
4. Remove air cleaners.
5. Remove blower belt.
6. Remove fuel pump.
7. Remove generator.
8. Remove vacuum balance tube at engine carburetor mounting pads.
9. Remove engine front shield.
10. Attach lifting rig to lifting adapter and at flywheel housing lifting eye.

Fig. 9 Engine lifting adapter mounted

11. Remove flywheel or flex plate.
12. Lift engine and place on repair stand.
13. Remove carburetors, cooling air throttle valve, fuel lines and oil level gauge.
14. Remove distributor and wires.
15. Remove coil and generator brace from cylinder head.
16. Remove engine upper shroud and left and right side shields.
17. Remove spark plugs.
18. Remove oil filter and generator adapter.
19. Remove blower and crankcase vent tube.
20. Remove crankcase cover and blower bearing.
21. Remove engine rear and lower shrouds and exhaust ducts.
22. Remove muffler bracket and shield.
23. Remove oil pan.
24. Remove exhaust manifolds. *Exhaust manifold-to-exhaust port sleeves are a press fit and should be removed with a soft hammer. If sleeves are removed they should be replaced with the next largest diameter sleeve.*
25. Remove engine front shrouds.
26. Remove engine rear mounting bracket and skid plate at engine rear housing.
27. Remove cylinder heads.
28. Remove hydraulic lifters.
29. Remove pistons and rods.
30. Remove cylinder oil baffle.
31. Remove pistons from cylinders.
32. Remove crankshaft pulley.
33. Remove camshaft and crankshaft.
34. Remove main bearings.

ENGINE, REASSEMBLE

Crankshaft

1. To install crankshaft gear, mount shaft in an arbor press and support it between front crankshaft throw and front journal.
2. Press on crankshaft gear and install two woodruff keys.
3. Position fuel pump eccentric and spacer on shaft.
4. Lubricate crankshaft and distributor drive gear and install distributor drive gear.
5. Install oil slinger with concave side away from distributor drive gear.
6. Install crankshaft and main bearings.

Camshaft

Camshaft bearing journal clearance should be .0015" to .0035" new and .002" to .004" used. If clearance is not within limits either the crankcase or camshaft should be replaced.

1. To assemble camshaft gear and thrust washer to camshaft, firmly support shaft at back of front journal in an arbor press.
2. Place thrust washer over end of shaft and install woodruff key in keyway.
3. Lubricate camshaft with hypoid lubricant.
4. Install camshaft gear and press into place until it bottoms against thrust washer.

Fig. 10 Installing camshaft in crankcase

Timing Gear Marks

1. Install camshaft, guiding camshaft thrust washer into groove in crankcase, Fig. 10, while indexing camshaft gear to crankshaft gear so that valve timing marks line up as shown in Fig. 11.
2. Install other half of crankcase onto crankshaft and camshaft and fasten both halves together. Tighten bolts to the proper torque and in proper sequence.
3. Check camshaft end play, which should be .002" to .007".
4. Check timing gear backlash which should be .002" to .004".
5. Install front crankshaft oil slinger on crankshaft gear with flange side toward crankcase. Install slinger retaining snap ring, using care to avoid scratching sealing surface.
6. Install main oil gallery plugs with Permatex 404 anti-freeze compound or its equivalent.
7. Install flywheel housing with new gasket and torque bolts to 20-30 ft. lbs.

Pistons, Cylinders and Rods

1. Push piston into cylinder with hammer handle while holding cylinder in one hand until it is slightly below top of cylinder bore. *Notch on piston top must be installed towards front of engine (flywheel end) on both banks.*
2. With pistons and cylinders installed, install rod bearings.

Fig. 11 Timing marks aligned for correct valve timing

Fig. 12 Showing tubes holding opposite cylinder in place while torquing connecting rod bolts

3. Position crankcase pins by turning crankshaft with pulley so that crankshaft journal is in line with piston and rod to be installed.
4. Place a piece of plastic hose with at least a $\frac{5}{16}$" diameter over each rod bolt to protect shaft journal.
5. Install a new copper cylinder gasket over cylinder pilot, Fig. 12.
6. Push piston with hammer handle while guiding cylinder bore pilot into crankcase. Remove plastic hose from rod bolts and install rod bearing and cap. Torque rod nuts to 20-26 ft. lbs.
7. Install cylinder holding tubes on cylinder studs to hold cylinder in place. Continue procedure until all cylinders and pistons are installed, Fig. 12.
8. Install cylinder air baffles with retaining springs, Fig. 13. *Air baffles are not interchangeable.*

Crankcase Cover and Blower Bearing

1. Install new gasket on crankcase.
2. Install crankcase vent and another crankcase gasket.
3. Install crankcase cover and blower bearing and torque bolts to 7-13 ft. lbs.
4. Install crankcase vent tube and gasket.

Fig. 13 Installing cylinder and piston. Tubes "A" and "B" are holding cylinders in place

Oil Pump Screen and Tube

If the original or a new oil pump screen and tube assembly is to be installed in the original crankcase, the outside diameter of the end of the tube will have to be tinned with solder before installing in crankcase.

1. Install oil pump screen and pick-up tube into cylinder case with pick-up screen positioned parallel to oil pan rails. Secure tube with clamp.
2. Coat threads on engine temperature and oil pressure sending units with anti-seize compound (Permatex 404) or its equivalent. Torque oil pressure unit to 45-65 ft. lbs. and temperature unit 35-45 ft. lbs.

Cylinder Head

Be sure all cylinder head gaskets are in cylinder head combustion chambers as shown in Fig. 14. Remove all cylinder retaining tubes from cylinder bank to which cylinder head is to be installed.

1. Install cylinder head, Fig. 15.
2. Install six flat washers and nuts on long studs, adjacent to intake manifold.
3. Install six new "O" rings, lubricated with lubriplate, in counterbore of cylinder head (location for rocker arm studs) and coat rocker stud bore with anti-sieze compound.
4. Install rocker arm studs, with threads coated with anti-sieze compound.
5. Tighten nuts and rocker studs in sequence shown in Fig. 16. Torque nuts and rocker studs to 27-33 ft. lbs.

Push Rod Oil Drain Tubes

1. Lightly oil hydraulic lifters and install in their proper bores.
2. Install push rod oil drain tubes through cylinder head, Fig. 17. Place "O" rings, one on each end of drain tube as shown. Oil "O" rings and push in place at lifter bore in crankcase and cylinder head.
3. Install push rods with side oil hole up into valve rocker socket, Fig. 18 (blue band end).
4. On early production engines, install push rod guides in place over rocker studs and push rods and tighten bolts. *On late production engines, push rod guides are installed under valve rocker studs.*
5. Install rocker arms, balls and nuts loosely in place. Adjust valve lash as outlined elsewhere in this section, after installing distributor.

Final Assembly

1. Install engine rear housing.
2. Install crankshaft pulley. After pulley bottoms in place, back off retaining bolt one turn and then torque it to 60-80 ft. lbs. *Do not drive pulley in place as this will damage crankshaft thrust bearing and crankcase.*
3. Install oil cooler.
4. Install exhaust manifolds.
5. Install oil filter and generator adapter.

Fig. 14 Installing cylinder head gaskets

Fig. 15 Installing cylinder head

Fig. 16 Cylinder head tightening sequence

Fig. 17 Installing push rod drain tubes

Fig. 18 Push rod installation

6. Install sheet metal removed.
7. Install wires, fuel lines, etc.
8. Install spark plugs.
9. Install oil pan. Check parting line to see if flywheel housing gasket is far enough up for good sealing.
10. Install fuel pump and add engine oil.

CYLINDER HEAD REPLACE

Engine In Truck

1962-63 Service Note

Cylinder head service procedures are the same as previous models except that the automatic choke control rod passes through the head to reach the thermostat and must be removed before the head can be removed.

Left Bank Head:

1. Drain crankcase oil.
2. Disconnect battery cables and ground connection to engine.
3. Disconnect radio ground strap.
4. Remove carburetor intake hose (connected to air cleaner and carburetor).
5. Remove carburetor accelerator return spring and disconnect accelerator rod from carburetor.
6. Disconnect left-side carburetor cross-shaft support (2 screws) from carburetor.
7. Disconnect fuel line at carburetor.
8. Remove carburetor.
9. Remove long stud from carburetor mounting.
10. Remove wires and spark plugs.
11. *Loosen* all engine side shield retaining screws. *Remove* screw from engine side shield under carburetor, attached to cylinder head. Remove engine side shield.
12. Remove oil cooler (this allows engine rear shroud freedom of movement during cylinder head removal).
13. Raise car on a hoist and attach a suitable lifting fixture to power train. *See requirements for lifting and supporting power train as outlined at the beginning of this section.*
14. Remove both engine side seal retainers and engine rear seal retainers.
15. Remove engine rear center shield and seal assembly.
16. Remove lower engine shroud.
17. Remove exhaust pipe-to-manifold nuts.
18. Open french locks on exhaust manifold and remove holding clamp nuts.
19. Remove exhaust manifold.
20. Remove engine rear mounting cotter pin, nut and washer from below body rear mounting bracket.
21. Remove rocker arm cover while holding a pan below to catch oil draining from cylinder head.
22. Remove rocker arms, push rods and push rod guides. *Present production engines require removal of valve rocker studs to remove push rod guides.*
23. Remove rocker arm studs, washers and "O" rings from head. Also, remove push rod guides from late production engines.
24. Remove "O" rings from bottom of push rod drain tubes with a pair of hooked tweezers. *To remove No. 5 exhaust push rod drain tube, it is necessary to remove the right side exhaust manifold.*
25. Remove retaining nuts and washers retaining head.
26. Carefully lower engine assembly approximately 3″ to clear cylinder head carburetor flange.
27. Remove cylinder head from crankcase studs.
28. Reverse above procedure to install the head and tighten head nuts in the sequence shown in Fig. 16.

Right Bank Head: Removal and installation of the right bank head is essentially the same as the left head, except the coil, oil pressure and oil temperature sending units must be disconnected. Also remove the choke heat pipe and choke fresh air pipe from the exhaust manifold.

CYLINDER HEAD ASSEMBLE

Cylinder heads are identical except for location of vacuum balance tube hose connector which is on one side of the carburetor mounting pad on the right bank and the other side on the left bank.

1. Install each valve coated with SAE 30 engine oil in the valve guide from which it was removed or to the valve guide it was fitted.
2. Lightly coat valve spring shim with petrolatum to hold shim in place and place on valve spring seat.
3. Set valve spring in place on shim. Place valve cap in position, compress valve spring and install valve locks. *Each valve spring must have a hardened shim (.020″ minimum) under it to protect aluminum surface. Service shims are available in .030″ thickness.*
4. Check installed height of valve springs, Fig. 19. Reseating valves raises the installed height of valve springs and, if excessive, will have the effect of weak valve springs. If installed height of springs do not come within the limits illustrated, install a .030″ shim. At no time should the spring be shimmed to give an installed height of less than the minimum limits.
5. Coat cylinder head and cylinder counterbore pilot with petrolatum to retain gasket and install new head gaskets, Fig. 14.

Fig. 19 Checking installed height of valve springs

Fig. 20 Adjusting valve lash

VALVES ADJUST

Engine In Truck

1. After engine has reached normal operating temperature, remove the valve cover and install a reworked valve cover (cut the top out of a used valve cover) and gasket on cylinder heads to prevent oil from running out.
2. With engine running at idle, back off valve rocker arm nut until rocker arm starts to clatter.
3. Turn rocker arm nut down slowly until the clatter just stops. This is the zero lash position, Fig. 20.
4. *Turn nut down ¼ turn and pause 10 seconds until engine runs smoothly. Repeat additional ¼ turns, pausing 10 seconds each time, until nut has been turned down one full turn from the zero lash position. This one turn preload adjustment must be done slowly to allow the lifter to adjust itself to prevent the possibility of interference between intake valve head and top piston.*
5. Adjust all valves in the same manner.

ROCKER ARMS REPLACE

Engine In Truck

1. Remove rocker cover and gasket.
2. Remove rocker arm nuts, balls and rocker arms.
3. Replace parts and adjust valve lash.
4. Install cover and gasket.

Fig. 21 Relation of valve and seat angles

PUSH RODS REPLACE

Engine In Truck

1. Remove valve cover and gasket.
2. Loosen valve rocker arms, balls and nuts from cylinder requiring push rod replacement.
3. Remove push rod and guide and install new push rod with .050″ side oil hole up into cylinder head.
4. Adjust valve lash and replace cover and gasket.

1962-63 Service Note

When a replacement push rod has a paint stripe at one end, this painted end must be installed in contact with the rocker arm. To provide durability, a hardened insert is incorporated in the rocker arm end of these push rods.

Near the color striped end of the push rod, a .050″ lubricant metering hole exists in the side wall. The push rod end having this hole must be assembled toward the rocker arm to provide oil flow to the valve train.

VALVES, REMOVE

Head Removed

With cylinder head removed, use a suitable valve spring compressor to compress the spring in order to take out the valve locks. Then remove valve spring cap, spring, shim and valve. Repeat this operation on each valve assembly. Place valves in a board with numbered holes to identify their location so that, if re-used, they can be returned to the original guide holes.

VALVE SPRINGS REPLACE

Engine In Truck

1. Drain crankcase oil.
2. Remove valve cover and gasket.
3. Remove rocker arm nut, ball and rocker arm.
4. Remove spark plug from cylinder requiring valve spring replacement and use compressed air to hold valves in closed position.
5. Install a nut on rocker stud and use a forked tool as a lever to compress valve spring far enough to remove valve locks. Then remove spring cap and spring.
6. Install spring on spring seat shim with cap. Compress spring and install valve locks.
7. Install rocker arm, ball and nut and adjust valve lash.
8. Install valve cover and gasket.
9. Install engine oil.

Head Removed

After taking out the valve springs, wash them with gasoline or other suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring testing fixture if one is available. Spring should be compressed to 1½″ at which height it should check 58 to 64 lbs. Weak springs affect power and economy and should be replaced if not within 5 lbs. of the above limit.

If a testing fixture is not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that stands shorter than the new spring used for comparison should be scrapped. Of course, cocked springs should also be discarded.

VALVE GUIDES

Head Removed

Valve guides are an integral part of the head and, therefore, cannot be removed. For service, guide holes can be reamed oversize to accommodate one of three service valves with oversize stems (.003″, .005″ and .010″).

After cleaning the valve guide holes, check the clearance with a dial indicator. Intake valve stem clearance should be .001″ to .004″ while exhaust stem clearance should be .002″ to .005″.

Clamp the dial indicator on one side of the rocker cover gasket rail, arranging the indicator so that movement of the valve stem from side to side (crosswise to head) will cause a direct movement of the indicator stem. The indicator must contact the side of the valve stem just above the cylinder head. With the valve head about $\frac{1}{16}$″ off its seat, move the stem of the valve from side to side with light pressure to obtain a clearance. By trying new valves in the guide holes it can be determined whether the valves should be replaced or the bores reamed and oversize valves installed.

Service Note

A mid-year change in 1961 and carried over into 1962 replaces the tapered stem exhaust valves with straight stem valves and releases valve stems of .003″, .010″ and .020″ oversizes for service.

VALVES, GRIND

Head Removed

In refacing valves take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced. In other words the valve head margin must be at least $\frac{1}{32}$″ otherwise the valve must be replaced. The margin is the area above the contact surface of the valve face. The valve seat width after refacing should be $\frac{1}{32}$″ to $\frac{3}{32}$″ for intake valves and $\frac{1}{16}$″ to ⅛″ for exhaust valves. Valve seat angle on all valves should be 45° and should be concentric within .002″ dial indicator reading. Valve face to seat angles are parallel as shown in Fig. 21.

Fig. 22 Hydraulic valve lifter

VALVE SEAT INSERTS

Head Removed

When reconditioning valves, the exhaust valve seat inserts in the cylinder head should be inspected. If either valve seat inserts or valve guide bores are beyond repair, the cylinder head should be discarded and replaced with a new one.

VALVE LIFTERS REPLACE

Engine In Truck

1. Drain crankcase oil.
2. Remove valve cover and gasket.
3. Remove engine lower shroud.
4. Remove rocker arms, balls, push rod guides, push rods and push rod drain tubes from cylinder from which valve lifter is to be removed.
5. Remove lifter with a strong magnet or:
   a. Remove snap ring retaining push rod seat and remove seat. Then remove lifter with a pair of pliers inserted in valve lifter snap ring groove.
   b. Remove oil pan and squirt lifter body with solvent to remove varnish from lifter body.
6. Install valve lifters well lubricated with engine oil.
7. Install push rod drain tubes with new "O" rings and set push rods in place on lifter seats with side oil hole up next to rocker arms.
8. Install push rod guides, rocker arms, balls and nuts, valve cover and gasket.
9. Install engine oil.

Fig. 23 Removing ridge and/or carbon from cylinder with ridge reamer

Lifters Out of Engine

1. Referring to Fig. 22, hold plunger down with a push rod and, using a small screwdriver or awl, remove push rod seat retainer.
2. Remove push rod seat and inertia valve, plunger and spring from lifter body.
3. Pull check ball retainer from plunger and remove ball and spring.
4. Clean all parts in solvent. If any parts are damaged, the entire lifter assembly should be replaced. The inertia valve in the push rod seat should move when the plunger is shaken.
5. Assemble lifter in reverse order of disassembly. Then compress plunger to open oil holes and fill plunger with SAE 10 oil. Work plunger up and down and refill.

EXHAUST MANIFOLD SLEEVES

The exhaust sleeves are a press fit into the exhaust manifold.

PISTONS & CYLINDERS

Engine Disassembled

1. Using a block of wood for a fixture, drill two holes, spaced to provide a location for two long bolts. Holes should be small enough to require driving the bolts into the wood block. Clamp wood block in vise.
2. Install cylinder over bolts on wood fixture. Holding cylinder with one hand, Fig. 23, insert ridge reamer and remove ridge and/or carbon from cylinder.
3. Check cylinder walls for out-of-round or excessive ridge at top of ring travel. If cylinders are found to have taper or wear in excess of .005″, the cylinder and piston must be replaced.

PISTON RINGS REPLACE

Engine In Truck

Bear in mind that cylinders and pistons are serviced as a unit and the operation outlined below is for replacing one or more pistons in one bank requiring ring replacement. It is not intended for complete piston and ring replacement.

1. Drain crankcase oil and remove cylinder head.
2. Remove cylinder from piston requiring new rings.
3. Remove old and install new rings. *Position oil control ring gap towards top of engine and compression rings with gap 45° from oil ring gap location. Rings must be installed with markings and inside bevel toward top of piston. Lubricate piston rings with engine oil and slide ring compressing tool, Fig. 24, over rings just enough to compress rings into piston.*
4. Reverse above procedure to install parts removed. Add engine oil, start engine and check for oil leaks.

PISTON PINS

Engine Disassembled

Piston pins should be capable of supporting their own weight in either piston boss when coated with light engine oil at 70° temperature. Higher or lower temperatures will cause false indications. *Pistons, pins and cylinders are serviced as assemblies.*

ROD BEARINGS REPLACE

Engine In Truck

1. Remove air cleaner element and carburetor intake hose.
2. Remove choke heat tube, choke fresh air hose and carburetor linkage.
3. Disconnect fuel lines at carburetor.
4. Remove left bank carburetor.
5. Disconnect choke link to choke assembly. Remove choke and air horn by removing nuts at legs of air horn support.
6. Disconnect spark plug wires.
7. Remove blower drive belt.
8. Disconnect fuel lines at fuel pump.
9. Remove carburetor cross shaft and vacuum balance tube.

Fig. 24 Installing piston rings with aid of ring compressor (J-8356)

Fig. 25 Installed length of crankcase and rear housing studs

10. Remove all engine upper shroud bolts and screws.
11. Remove screws on each side of front engine shield.
12. Disconnect cooling air throttle valve thermostat rod and remove cooling air throttle valve.
13. Remove all fuel lines.
14. Remove engine upper shroud, tipping front lip up so it clears front engine shield.
15. Remove blower pulley and blower.
16. Remove crankcase cover, gaskets and crankcase vent.
17. Remove spark plug from cylinder requiring new rod bearing and remove rod cap and bearing insert. Use a piece of $\frac{5}{16}$″ plastic hose on each rod bolt to protect crankshaft journals from being scratched or marred.
18. Reverse above procedure to install parts removed. While tightening upper shroud bolts, rotate blower and check for interference at blower to upper shroud. Add engine oil, start engine and check for oil leaks.

Engine Disassembled

Rod bearing inserts are available in standard sizes and undersizes of .001″, .002″, .010″ and .020″. These bearings are not shimmed and when clearance becomes excessive the next undersize bearing insert should be used. *Do not file rod or caps in an attempt to fit bearings.*

Rod bearing clearance is checked with Plastigage in the same manner outlined for main bearings. If flattened Plastigage measurement is not over .003″ (worn) or .002″ (new) or not less than .001″ the fit is satisfactory.

CRANKCASE

Engine Disassembled

1. Remove two oil gallery plugs located at flywheel housing end of crankcase. These passages should be cleaned with solvent.
2. Check cylinder pilot bores and bearing surfaces in each half of crankcase for nicks, cracks or other damage that would interfere with the proper fit of component parts.

3. Do not use scrapers or other sharp tools to clean gasket surfaces. A good cleaning solvent should be used to dissolve gasket material or varnish that may adhere to the surfaces.

Stud and Thread Repairs

Always use anti-seize compound (Permatex 404 or equivalent) on all threads entering aluminum.

To replace crankcase studs, install long and short studs as indicated in Fig. 25. Studs are available in oversizes of .003", .006" and .009".

It should require a torque of 10 to 30 ft. lbs. to install studs. If torque is less than 10, another selected stud should be used.

Heli-coils for thread repairs are available at local auto parts jobbers and should be installed to Heli-Coil prescribed methods.

All cylinder studs installed in crankcase adjacent to the main bearing webs have blind holes while others do not.

MAIN BEARINGS

Engine Disassembled

Whenever the crankcase is parted, the bearings and crankshaft journals should be inspected. If upon inspection one half shows evidence of fatigue, distress abrasion, erosion, scoring or the like, both crankcase halves should be replaced. *Never should one half be replaced without replacing the other half.*

If the running clearance of a bearing is too great with used bearing inserts, it will be necessary to replace both bearing halves. Should this become necessary the crankshaft journal should be checked with a micrometer for out-of-round, taper or undersize dimensions.

Service Note

To prevent the possibility of mismatch of the bearing thrust flanges on rear main bearings, the left half of the bearing only has thrust flanges. The unflanged half is installed in the right half of the crankcase. This change was incorporated during 1962 production.

Fig. 26 Crankcase tightening sequence

Fig. 27 Oil filter and oil cooler by-pass valve installation

Main Bearing Clearance

Main bearing clearance is checked with Plastigage, a wax-like material, available at auto parts jobbers.

To assure proper seating of the bearings, all crankcase bolts must be at their specified torque. Eight long $\frac{7}{16}$" bolts 42-48 ft. lbs., and three $\frac{5}{16}$" bolts 7-13 ft. lbs. Hold bolt head on $\frac{7}{16}$" bolts while tightening the nut. Do not tighten at bolt head. Fig. 26 shows tightening sequence. To check main bearing clearance, proceed as follows:

1. Starting with rear main bearing, remove one half of the crankcase while the other is supported on its side. Wipe oil from bearings and journal.
2. Place a strip of Plastigage the full width of the bearing (parallel to crankshaft on journal). *Crankcase split line surfaces must be free of nicks and foreign matter.*
3. Install other half of crankcase with bearings and evenly tighten crankcase bolts to proper torque. *Do not rotate crankshaft while Plastigage is between bearing and journal.*
4. Remove one half of crankcase. Then measure the width of the flattened Plastigage with the graduated scale on the edge of the Plastigage envelope.
5. If the flattened Plastigage is not over .004" (worn) or .003" (new) or less than .001" the bearing insert is satisfactory. If not within these limits replace bearing insert.
6. A .002" undersize bearing may produce the proper clearance. If not, it will be necessary to regrind the crankshaft journal for use with the next undersize bearing. Bearings are available in undersizes of .001", .002", .010" and .020".
7. Proceed to the next bearing. After all bearings have been checked and installed, rotate the crankshaft to see that there is no excessive drag.
8. Check the end play by forcing the crankshaft to the extreme forward position. End play should be .002" to .006".

OIL PAN REPLACE

Engine In Truck

1. Drain crankcase oil and remove all bolts retaining oil pan to crankcase. Remove pan and discard gasket.
2. Install oil pan and torque retaining bolts to 3½-5 ft. lbs.

OIL PUMP GEARS REPLACE

Engine In Truck

1. Drain crankcase oil.
2. Place a piece of hardwood between oil pan rail and Power Train Cradle (J-7894). Install wood block adjacent to engine skid plate. Installation of wood block will allow easy removal of skid plate.
3. Disconnect engine rear mount and remove engine rear shield seal and center shield. Remove bolts from exhaust air ducts connected to the engine rear center shield plate.
4. Lower engine about 1" to clear rear mount.
5. Remove rear mounting bracket and engine skid plate.
6. Remove oil pump cover and gears.
7. Reverse above procedure to replace parts removed. Torque mounting bracket nuts to 20-30 ft. lbs. and torque rear mounting nut to 40-60 ft. lbs.
8. After completing installation of remaining parts, add engine oil, start engine and check for leaks.

OIL PUMP REPAIRS

Engine Disassembled

1. When assembling the oil pump to the engine rear housing, install the idler gear on the shaft. Idler gear shaft should be .010" to .020" below gasket surface.
2. Place drive gear and shaft in pump housing.
3. Check projection of oil pump gears above gasket surface; this should be .0045" maximum and .0025" minimum. Clearance between gears and housing should be .005".
4. Lubricate pump gears before installation. Install pump cover and tighten bolts.
5. Install a long screwdriver down the

Fig. 28 Installing oil pressure regulator stop groove pin

Fig. 29 Installing oil gallery plug

distributor mounting hole in the engine rear housing and turn oil pump drive shaft to see that pump turns freely.

6. Install pressure regulator valve, spring, gasket and plug.

OIL PUMP PRESSURE REGULATOR REPLACE

Engine In Car

1. Drain crankcase oil.
2. Remove right side exhaust air duct.
3. Remove pressure regulator plug, nylon gasket, spring and valve.
4. Install regulator parts, exhaust air duct and crankcase oil. *To check oil pressure, remove plug on top of oil filter and generator adapter, and install an oil pressure gauge. Start engine, check pressure, which should be 35 psi, and check for oil leaks.*

OIL COOLER & BY-PASS VALVES

Engine Disassembled

1. Referring to Fig. 27, remove oil filter by-pass valve by catching the inner edge of the valve with a suitable hook or small screwdriver.
2. Install the new filter valve with the spring *up* in the adapter housing.
3. Remove the oil cooler valve in the same manner as the filter valve. However, the valve spring should be installed *down*.

OIL COOLER, CLEAN

Engine In Truck

Remove the cooler access hole cover (under generator) and brush foreign particles away from oil cooler fins. Insert an air hose gun under the cooler and blow up through cooler fins.

OIL COOLER REPLACE

Engine In Truck

1. Remove screws retaining oil cooler to engine shrouds, shields and cylinder head.
2. Remove cooler access hole cover (beneath generator) and remove long oil cooler mounting bolt and cooler.
3. Remove and discard worn seals from oil cooler adapter.
4. Invert cooler and allow oil to drain. Clean cooler fins with an air hose before and after cleaning in solvent.
5. Reverse above procedure to install. Tighten long retainer bolt 8-12 ft. lbs. Start engine and check for oil leaks around cooler and seal location.

OIL PAN

Engine In Truck

1. Drain crankcase oil.
2. Remove bolts securing oil pan to crankcase.
3. Remove oil pan and discard gasket.
4. Installation is done in reverse order and bolts are tightened to *40-60 inch lbs.*

OIL FILTER & GENERATOR ADAPTER

Engine In Truck

1. To remove, release pulley belt tension at idler pulley and remove blower pulley belt. Disconnect battery ground and generator harness.
2. Remove generator and bracket.
3. Disconnect fuel lines at pump.
4. Remove bolts around oil filler tube; then remove all remaining bolts from adapter.
5. Remove adapter with fuel pump, oil filter and idler pulley as a unit.
6. Remove adapter gasket.
7. Reverse above procedure to install and torque adapter bolts to 7-13 ft. lbs.

CRANKCASE VENT TUBE REPLACE

Engine In Truck

1. Remove engine upper shroud and blower pulley.
2. Remove retaining bolts and remove vent tube.
3. Install a new cork gasket over vent tube end, and insert in crankcase cover.
4. Install vent tube clamp and tighten bolt securely.
5. Install blower pulley and engine upper shroud assembly.

CRANKSHAFT PULLEY & ENGINE REAR HOUSING SEAL REPLACE

Engine In Truck

On some engines the rear housing seal is installed with the flange on the inside, in which case the engine will have to be removed from the car and rear housing removed. If the flange is on the outside, proceed as follows:

1. Drain crankcase oil.
2. Disconnect battery cable to engine.
3. Remove all side shield seal retainers.
4. Remove engine rear center shield.
5. Remove engine skid bolt and attach Power Train Cradle (J-7894) to bottom of engine with car on a hoist.
6. Remove engine rear body grille and engine rear mount.
7. On standard transmission cars remove clutch return spring and disconnect clutch control cable and clutch pull rod.
8. Loosen outboard stud nut and slide it part way out of engine front mounting bracket slot.
9. Remove shift rod coupling.
10. Loosen front mounting nuts and lower engine until nuts are flush with end of studs (do not remove nuts.)
11. Lower engine far enough to remove engine rear mounting bracket.
12. Remove oil filter and pulley belt.
13. Remove crankshaft pulley with a suitable puller. *Install bolts in pulley hub a depth of ¼" only, otherwise the bolts will damage the rear housing seal.*
14. Remove engine rear housing seal by prying on its outer edge with a couple of screwdrivers. *The lips of seal are packed with high melting cup grease for the life of the seal.*
15. Reverse above procedure to install parts removed. Add engine oil, start engine and check for oil leaks.

ENGINE REAR HOUSING

Engine Disassembled

When replacing the engine rear housing as a new unit, the following operations are required.

1. Install groove pin, Fig 28, which holds oil pump pressure regulator valve in place.
2. Install oil pump gallery plug flush with counterbore, using sealing compound, Fig. 29.
3. Install new rear housing seal.
4. Install distributor holding stud 1⅛" measured from distributor pad on engine rear housing.

FLYWHEEL HOUSING SEAL

Engine Disassembled

1. Tap seal out of housing with a wood or fibre drift.
2. Clean flywheel housing seal surface with solvent and check surface for nicks or damage.
3. Lubricate outer seal surface (beaded area) with lubriplate or petrolatum and install with a suitable driver. *If seal is removed and still usable, pack sealing lips with a good grade of cup grease with a high melting point (350°). New seals are packed with this type grease to last the life of the seal.*

Fig. 30 Blower bearing and crankcase cover assembly

Fig. 32 Ignition wiring

BLOWER BEARING, BLOWER & CRANKCASE COVER

Engine In Truck

1. Disconnect battery ground cable.
2. Disconnect accelerator linkage and fuel lines.
3. Remove oil level gauge and fresh air choke at air cleaner. Remove choke pipe.
4. Remove air cleaner, air horn and support.
5. Remove carburetor vacuum balance tube and retaining strap at engine upper shroud.
6. Remove pulley belt and distributor wire harness.
7. Disconnect cooling air throttle valve lever swivel.
8. Remove engine upper shroud and thermostat rod as a unit. An alternate method is to remove the lower left shroud and remove clip from thermostat rod; then remove thermostat rod from engine upper shroud.
9. Remove blower pulley and blower (4 bolts) from blower bearing hub assembly.
10. Remove crankcase cover bolts and washers.
11. Remove crankcase - to - crankcase vent gasket and crankcase vent.

Blower Bearing Replace

1. While supporting crankcase cover, press blower bearing shaft out of blower.
2. Install new blower bearing hub assembly in crankcase cover, using hypoid lubricant on bearing shaft.
3. Press on shaft of blower bearing to a height shown in Fig. 30. *Do not press on bearing outer or inner race.*

Fig. 31 Crankcase cover (C), vent (A) and gaskets (B)

Installation of Blower

1. Assemble crankcase cover, vent and gaskets as shown in Fig. 31.
2. Install blower and pulley bolts and torque to 20-25 ft. lbs.
3. Install engine upper shroud fuel lines and cooling air throttle valve assembly and tighten all retaining bolts. *When tightening upper shroud bolts, turn blower several times to make sure blower edge does not rub against upper shroud.*
4. Install remaining parts in the reverse order of removal.

BLOWER BEARING REPLACE

Crankcase Cover Removed

1. While supporting crankcase cover press blower shaft out of cover.
2. Install a new blower bearing hub in cover, using hypoid lubricant on bearing shaft.
3. Press on shaft of blower bearing and press assembly in place to a height of $4\frac{15}{32}$" to $4\frac{31}{64}$" parallel to cover gasket rails. Do not press on bearing inner or outer race.

DISTRIBUTOR REPLACE

Engine In Trucks

To remove distributor, disconnect primary wire from coil. Remove distributor cap and vacuum line from distributor. Mark position of rotor arm on housing so that distributor may be reinstalled in same position. Unfasten and remove distributor from engine.

If necessary to remove secondary leads from distributor cap, mark position on cap tower for lead to No. 1 cylinder or see Fig. 32.

When installing distributor, turn rotor about ⅛ turn counterclockwise past the mark previously placed on distributor housing. Push distributor down into position in block with housing in normal installed position. It may be necessary to move the rotor slightly to start gear into mesh with camshaft gear but rotor should line up with mark when distributor is down in place. Fasten distributor in place and check ignition timing.

IGNITION TIMING

If a timing light is to be used to set ignition timing, disconnect the vacuum advance pipe to the carburetor and place a piece of tape over open end of pipe. *This is important as carburetor trouble can affect timing adjustments.*

Lacking a power timing light, an accurate method of setting ignition timing with the engine stopped is with the aid of a jumper light. Be sure to use a light bulb that corresponds with the system voltage of the vehicle.

1. Remove distributor cap and rotor and see that the breaker gap is set according to specifications.
2. Rotate engine until No. 1 cylinder is at the ignition timing point as indicated by the timing pointer and timing mark being lined up with each other.
3. Connect the jumper light between distributor ignition terminal and ground.
4. Turn on ignition switch.
5. Loosen distributor and turn it in the direction of normal rotation until the points just close (light out). Then slowly turn distributor in the opposite direction just to the exact point that the light goes on. Tighten distributor in this position.

GENERATOR REPLACE

Engine In Car

Disconnect ground cable from battery, and wires from generator terminals. Remove drive belt, three attaching bolts and remove generator from engine.

Installation

1. Place generator in position and install bracket, leaving nuts loose.
2. Place blower belt over generator pulley but do not tighten idler bracket at this time.

3. Tighten two generator-to-engine oil filter attaching bolts and torque to 15-22 ft. lbs.
4. Snug up mounting bracket-to-generator bolt and nut (at commutator end) but do not tighten so that the bracket cannot move. Then finger tighten bracket-to-cylinder head bolts.
5. Tighten generator bracket-to-engine rear bolt to 15-22 ft. lbs.
6. Tighten mounting bracket-to-generator bolt (at commutator end) to 8-11 ft. lbs.
7. Tighten generator bracket-to-engine front bolt to 15-22 ft. lbs.
8. Adjust idler pulley so that there will be a ⅜" deflection with a 15 lb. push midway between blower and idler pulley. Tighten idler pulley.
9. Connect generator wires to their proper terminals. On radio equipped cars, connect radio by-pass condenser to the armature (A) terminal —not to field (F) terminal.

STARTER REPLACE

Engine In Car

Disconnect wires and cable from starter. Unfasten and remove starter by pulling it forward to clear housing.

Revese removal procedure and check starter operation.

Carburetor Section

Fig. 1 Exterior views of 1962-63 carburetor

Fig. 2 Two views of 1961 carburetor

CARBURETORS

1962-63

These engines use two identical automatic choke, single barrel carburetors, Fig. 1, one located on each intake manifold. Each carburetor is separated from the manifold by an insulator block.

The automatic choke mechanism consists of a thermostat control coil mounted to the lower side of the cylinder head and linked directly to the carburetor choke valve shaft. A vacuum diaphragm, mounted on the carburetor air horn, replaces the conventional choke vacuum piston, to provide the start and run position of the choke valve. A fast idle cam is provided to control engine speed during warm-up.

1961

The Corvair engine uses two identical Rochester Model "H" manual choke, single-barrel carburetors, Fig. 2. Each carburetor is separated from the engine manifold by an insulator block. The two carburetor thottle shaft levers are connected by a cross shaft which is actuated by the accelerator linkage. Careful adjustment must be made to insure that the carburetors are properly synchronized. An oval air duct runs laterally across the forward engine compartment connecting two air cleaners, one at each carburetor.

SYNCHRONIZE CARBS.

1962-63

1. Perform the following adjustments on each carburetor (in sequence) with both throttle rods disconnected at the cross shaft, choke control rods disconnected at choke levers and with engine shut off.
2. Back idle speed screw away from throttle lever. Open choke valve so throttle lever does not ride fast idle cam. Place a .003" feeler gauge between idle speed screw and throttle lever. Turn screw in until it just

contacts gauge and then continue for 1½ turns more to set throttle valve.

3. Turn idle mixture screw lightly to its seat and back out 1½ turns.
4. Connect throttle rod to right-hand carburetor cross shaft lever, using clip.
5. To connect left carburetor, rotate cross shaft (with accelerator rod) to insure positive closing of right carburetor throttle valve. Adjust throttle rod length in swivel until rod freely enters hole on carburetor cross shaft lever. Then shorten rod one more turn in swivel. Secure rod with clip. *It may be necessary to hold choke valve open so fast idle cam is clear of throttle lever.*
6. The carburetors are now mechanically synchronized. Any further idle speed or mixture adjustment must be duplicated on both carburetors.

1961

1. Detach and lift off air cleaner and air hoses as a unit.
2. Disconnect throttle rods from each carburetor.
3. Fully back off each idle speed screw on each carburetor so that each throttle valve is fully closed.
4. Place a .003" feeler between idle speed screw and throttle lever. Turn screw down until it just holds gauge. Remove gauge and turn screw one complete turn more. Perform this operation on each carburetor.
5. Reconnect the throttle rod to the right carburetor and the throttle rod swivel to the left-hand cross shaft lever. Be sure the left-hand cross shaft lever is turned fully clockwise to insure that the right hand carburetor throttle valve is fully closed. Lifting up on the left-hand carburetor throttle rod, adjust the swivel at the top of the rod so that it freely enters the hold in the cross shaft lever.
6. The two carburetors are now synchronized. Any further curb idle speed screw adjustment must be duplicated on both carburetors.

Positive Crankcase Ventilation

When there is a complaint of carburetor troubles and the car is equipped with a Positive Crankcase Ventilator Unit, it is advisable first to check the operation of this unit before servicing the carburetor. For data on this unit, see the *Tune Up Chapter*.

ROCHESTER CARBURETOR ADJUSTMENTS

★See Tune Up Chart for hot idle speed.

Year	Carburetor Model	Idle Adjustments★			Float Level	Float Drop	Vacuum Diaphragm Adjust	Unloader Setting	Pump Rod Setting	Choke Setting
		Mixture Screws Turns Open	Fast Idle Speed	Dashpot Plunger Clearance

ROCHESTER NOTES

Fig. ①—Float level. If float has no dimple, take measurement from center of float.

Fig. ②—Float drop.

Fig. ③—With throttle valves completely closed, bend pump rod as shown until index line on upper pump lever just aligns with sharp edge of air horn casting.

④—With throttle valves wide open there should be the clearance listed between top of choke valve and adjacent wall of air horn. To adjust, bend unloader tang.

⑤—With choke wide open, clearance between fast idle screw and pad (tang) on throttle lever should be .015" (.010" on 1960) on manual transmission and .030" on automatic transmission jobs. Adjust fast idle screw as required.

⑥—With engine stopped and throttle lever on second highest step of fast idle cam, bend tang to obtain the clearance listed between idle speed screw and throttle lever.

⑦—Hold vacuum diaphragm arm in against diaphragm. Clearance between lower edge of choke valve and wall of air horn should be as listed. If necessary to adjust bend diaphragm link. After this setting, throttle lever fast idle tang should rest on second highest step of fast idle cam. If not, adjust by bending outer choke shaft lever tang.

⑧—With choke control rod disconnected, hold choke valve closed. While holding control rod against stop in choke thermostat bracket, adjust upper choke control rod until it freely enters hole in choke shaft lever. Always turn vertical portion (not offset portion) of control rod. After engine warm-up, choke valve should be open and fast idle cam should clear throttle lever.

Clutch and Manual Shift Transmissions

CLUTCH LINKAGE

1. Refer to Fig. 1. First be sure the pedal has at least ¾" travel before clutch release bearing engages clutch diaphragm springs.
2. Disconnect rear clutch return spring.
3. Remove rear cable clevis.
4. Allow clutch fork pull rod lever to hang free.
5. Pull rearward on cable clevis to insure that all slack is removed from that point forward.
6. Manually pull clutch fork pull rod until slack is taken up at clutch fork.
7. Adjust pull rod clevis to align holes in both clevis.
8. Unscrew clevis 3½ turns, lengthening rod by $\frac{5}{32}$".
9. Tighten pull rod clevis jam nut. Line up holes in cable clevis, pull rod clevis and clutch fork pull rod

Fig. 1 Clutch linkage

Fig. 2 Three speed transaxle (transmission and axle)

Fig. 3 Manual shift three speed transmission

lever. Insert clevis pin and retainer clip.

10. Install clutch return spring.

CLUTCH REPLACE

1. Remove engine, axle and transmission from the car and separate the axle and transmission from the engine as outlined in the *Power Train Section.*
2. The clutch fork, ball stud and clutch release bearing are removed with the axle housing.
3. Disconnect clutch fork from ball stud and remove clutch release bearing from shaft.
4. Remove 6 clutch attaching bolts, one turn at a time, until clutch spring pressure is released. Then remove clutch from engine.
5. Reverse above procedure to install the clutch, being sure the cushion springs of the clutch disc are located on the flywheel side of the driven plate hub.

MANUAL TRANSMISSION

In essence the Corvair transmission is a conventional synchromesh type except for the use of concentric input and output shafts and its mounting on the differential carrier, Fig. 2.

Because of its mounting on the differential carrier, the mainshaft is hollow to permit the passage of the clutch shaft to the front of the transmission to the clutch gear. The clutch gear drives the counter gear and the remaining power flow sequence is identical to the conventional three speed transmission.

Transmission Replace

Instructions for the removal of the power train from the vehicle and the separation of the transmission from the power train are provided in the *Power Train Section.*

Transmission Disassemble

1. Remove front cover plate and clutch gear bearing snap ring, Fig. 3.
2. Remove clutch gear and bearing (special puller J-8136).
3. Remove top cover.

Fig. 4 Shift forks installed

4. Remove snap ring from mainshaft groove.
5. Drive or press mainshaft out of transmission.
6. Remove mainshaft parts by lifting out through top of case.
7. Expand snap ring and remove mainshaft rear bearing.
8. Drive countershaft out from hole in front of case, being sure to account for 25 needle rollers at each end.
9. Drive reverse idler shaft lock pin into the shaft; then drive the shaft out of the case through the hole at the rear of the case. The plug at the front of the case will be driven out by the shaft.
10. Remove detent cover and remove shift forks if necessary, Fig. 4.

Transmission Repairs

Reverse Idler Gear Bushings—Because of the high degree of accuracy to which these parts are machined, the bushings are not serviced separately. Check bushings for excessive wear by using a narrow feeler gauge between shaft and bushing. Proper clearance is from .002" to .004".

Countergear Needle Bearing—If wear is indicated on these bearings, they should all be replaced as well as the countershaft.

Clutch Gear Bearing—As the clutch gear bearing is removed as a unit, it will be necessary to drive the clutch gear out of the bearing if replacement of either the gear or bearing is required.

Clutch Sleeve and Synchronizer Rings—

Fig. 5 Removing synchronizing ring

1. Remove first and reverse sliding gear.
2. Turn synchronizer ring in clutch sleeve until ends of ring retainer can be seen through slot in clutch sleeve.
3. Expand retainer into counterbore in clutch sleeve, Fig. 5. This raises retainer from groove in ring so ring may be slipped out.
4. Check synchronizer cones for wear or for being loose in clutch sleeve. If cones are damaged in any way, it will be necessary to replace the clutch sleeve and both synchronizer rings. Clutch sleeve should be replaced if there is more than .030″ end play between cone and snap ring.

Fig. 6 Position of energizing spring

5. Inspect synchronizer rings for smoothness.
6. Place the synchronizer rings in the cones and check with thumbs to see that rings do not rock. Excessive rocking indicates a poor fit between rings and cone, which will not permit proper synchronizing of gears during shifting.
7. Assemble synchronizer parts, being certain retainers seat in groove all the way around rings so rings will turn freely.

Synchronizer Energizing Springs—Under normal operation it should never be necessary to replace the energizing springs. However, should a spring be removed for any reason, a new spring should be installed. The spring may be removed by slipping a thin blade under the spring and raising it sufficiently to slide it off over the clutch gear teeth.

Install the new spring as shown in Fig. 6, thus keeping the spring from turning in its groove.

Transmission Assemble

1. Referring to Fig. 3, lubricate manual control shaft with oil and insert through seal in case. Position actuating finger and secure to shaft with two lock tabs and capscrews.
2. Install detent spring and ball, Fig. 7, in detent cavity. Tap to insure spring is resting on bottom of cavity.
3. Insert first and reverse shift fork through case, slip fork on shaft and secure fork to shaft with roll pin.
4. Insert interlock in detent cavity.
5. Insert second and third fork shaft through case and slip fork onto shaft. Twist shaft so its interlock groove is 90 degrees from the interlock; then fully insert shaft and twist shaft so interlock notch is engaged by interlock. Secure shift fork to shaft with roll pin.
6. Insert detent ball and spring for second and third shift fork, and install detent cavity cover and gasket.
7. Place some cup grease in roller bearing area of each end of countergear and install 25 rollers in each end. Grease will hold rollers in place while installing.
8. Apply grease to bearing thrust washers and countergear thrust washer and place one at each end of countergear. Tab on each washer should be positioned so as to align with notches in case.
9. Insert countergear in bottom of case.
10. Lubricate and insert countershaft in case.
11. Coat thrust washer and needle thrust bearing with grease and position them on reverse idler gear. Needle bearing against end (rear) with chamfered gear teeth. Coat bushings with transmission lubricant.
12. Place reverse idler gear in case with thrust bearing toward rear.
13. Install reverse idler shaft from rear, making sure lock pin hole in shaft lines up with hole in case at same angle.
14. Use new idler shaft lock pin and drive it in approximately $\frac{1}{16}$″ beyond flush with case.

Fig. 7 Installing detent spring and ball for first and reverse shift fork shaft

15. Install mainshaft rear bearing in case until bearing contacts retainer ring in case. Then expand retainer and tap bearing until retainer ring seats in bearing groove.
16. Assemble mainshaft components, Fig. 8.
17. From the front, insert mainshaft through bores of second and third speed clutch and second speed gear; then install thrust washer on mainshaft with oil grooves toward gear.
18. Tap front of mainshaft until ring groove is accessible behind rear bearing and install snap ring. Check fit of snap ring by inserting feeler between snap ring and bearing inner race. End clearance must be .004″ maximum. Thrust washers are available in four thicknesses ranging from .086″ to .097″.
19. Place some cup grease in mainshaft pilot hole of clutch gear and install roller bearings and small spacer. Then install large spacer and remaining roller bearings.
20. Align synchronizer lands with clutch gear blank teeth.
21. Tap clutch gear bearing into case. Open retainer ring and fully seat bearing as indicated by seating of retainer ring in bearing groove.
22. Install front cover plate and gasket.
23. Install top cover and gasket.
24. Install expansion plugs in case openings at rear of manual shift shaft and reverse idler gear.

Fig. 8 Mainshaft assembly

Powerglide Section

DESCRIPTION

The Corvair Powerglide transmission, Fig. 1, consists of an air-cooled, three element torque converter which drives through an automatic, two-speed planetary transmission.

As shown, the transmission is integrated to the differential carrier to form a Transaxle. As a result, the converter is remote from the main transmission, being separated by the differential carrier. Two shafts run axially through the hollow pinion shaft; one from the converter cover hub to the front pump and the other from the turbine to the input sun gear to transmit converter torque to the transmission gear box.

Excepting the converter location, mechanical components of the Corvair Powerglide are generally scaled-down versions of comparable parts in the conventional Powerglides used on Chevrolet cars. The use of a plate-type reverse clutch and a welded converter with integral starter driven gear are obvious exceptions.

MAINTENANCE & ADJUSTMENTS

Adding Oil

Oil level should be checked every 1000 miles. Oil should be added only when the level is near the "ADD" mark on the dipstick with oil at normal operating temperature. The oil level dipstick is located in the right front of the engine compartment. *The difference in oil level between "FULL" and "ADD" is one pint.*

To check oil level accurately, the engine should be idled with the transmission oil at normal operating temperature and the control lever in Neutral position. Oil level should be maintained no higher than the "FULL" mark on the dipstick. Do not overfill as foaming and aerating of the oil will result because the planetary unit will be running in oil, causing improper application of the band or clutches.

Draining and Refilling

No periodic draining of the transmission oil is recommended.

When the transmission requires repairs, drain the oil by loosening the filler tube attaching nut in the oil pan and allow the oil to drain (no drain plug is provided).

To refill the transmission, tighten the filler tube nut and add 4 pints of transmission fluid, using a suitable filler tube and funnel. Start engine and allow it to idle in Neutral for 3 to 5 minutes to warm the transmission fluid. Then add oil as required to bring the level to the "FULL" mark on the dipstick. Assuming that the converter was not drained (since it is welded) and allowing for nominal spillage or draindown, approximately 6 pints are required for a refill.

SHIFT LINKAGE

Check Operation

If improper shift linkage adjustment is suspected, a check can be made

Fig. 1 Corvair Powerglide

Fig. 2 Shift linkage check diagram

Fig. 3 Adjusting manual valve linkage

quickly without any disassembly as follows:

1. Start engine and allow to run for 2 to 3 minutes to warm up the transmission fluid.
2. With engine at normal idle speed, very slowly move range selector lever up from "N" to"R" and note by feel the point at which the reverse clutch applies. Properly adjusted, the reverse clutch should apply at the peak of the tooth separating Neutral and Reverse detents, Fig. 2.
3. Make the same check as in Step 2 while moving the selector lever from "N" toward "D". Properly adjusted, the low band should apply as the selector lever follower is felt to be at the tooth peak separating Neutral from Drive and full Drive detent.
4. Unless the shifts are obtained at the points illustrated, the shift linkage should be adjusted with Gauge J-8365, Fig. 3.

Adjustment

1. Drain oil and remove oil pan.
2. Place selector lever in "D".
3. Insert Gauge J-8365 into manual valve bore as shown in Fig. 3 with tab of gauge upward so it engages to forward port of valve body as shown in inset.
4. With gauge in place, push forward on manual valve levers. Properly adjusted, the gauge will be held in place horizontally without being supported.
5. If readjustment is required, loosen lock screw and push manual valve levers forward so that gauge is held in this attitude. Recheck adjustment as in Step 4.
6. When satisfactory adjustment is obtained, install oil pan and filler tube; then refill transmission with oil as described above.

Neutral Safety Switch Adjustment

Properly adjusted the neutral safety switch should prevent engine cranking when the ignition switch is turned to "Start" with the selector lever in any position other than "N".

To adjust, loosen switch mounting screws and place range selector lever in "N". Push switch in a direction towards front of vehicle as far as possible to extend plunger. Insert gauge (.680-685") between end of plunger and switch; then move switch tightly against gauge and plunger and tighten two attaching screws while holding in this position. *A gauge* 1" x 13/32"x.680-.685" *can be made from steel stock.*

Throttle Valve Linkage

As special linkage is not used to actuate the transmission throttle valve, refer to the carburetor portion of the *Engine Section* for adjustment procedure.

Low Band Adjustment

As no periodic adjustment of the low band is recommended, access to the adjusting screw has been provided from inside the vehicle via the parcel compartment area behind the rear seat.

To gain access to the low band, remove the parcel shelf and the plug covering the access hole in the floor pan.

Adjustment of the low band requires an improvised tubular hex ¾" socket approximately 4½" to 6" long. Probably the simplest way to fabricate this tool would be to weld two ¾" tubular stamped steel spark plug wrenches together.

To adjust, loosen the lock nut and tighten the adjusting screw *to 35 to 45 inch lbs., then back off 4 complete turns exactly.* While holding the adjusting screw stationary by means of the socket, inserted through the improvised wrench, tighten the lock nut securely.

"In Truck" Repairs

CONTROL CABLE REPLACE

Remove tunnel covers and detach cable as suggested by Fig. 4. Install new cable as follows:

1. Lay cable out beneath car in its correct relationship.
2. Insert cable up into passenger compartment. Cable must then be routed *under* parking brake cable and then *over* parking brake pipe to prevent possibility of brake cable riding against shift cable.
3. Connect shift cable to range selector.
4. Shift range selector to "D" and secure cable to base of toe-pan.
5. Complete installation as shown in Fig. 4, being sure to bow cable to center line of vehicle to guide cable through hole in engine front support.

Cable-to-Transmission Installation

Install O-ring seal on cable, having lubricated it with Lupriplate. With throttle rods disconnected from throttle valve lever on transmission, rotate throttle valve lever its full limit counterclockwise and insert cable ball into slot of manual valve lever. Fully seat O-ring and secure installation by installing capscrew and lockwasher, Fig. 5.

Fig. 4 Shift control cable routing

Fig. 6 Cable installation check diagram

Checking Installation, Fig. 6—Once fully tightened, exert a slight hand pressure in the counterclockwise direction and check that the hole in the notched arm of the throttle valve lever is *below* the transmission oil pan rail the dimension indicated by the arrows, Fig. 6 (3/8" plus or minus 1/16"). If hole is above pan rail, cable installation is faulty and must be rechecked.

VACUUM MODULATOR

The vacuum modulator is mounted on the right side of the transmission and can be serviced from beneath the vehicle. Disconnect the vacuum hose and unscrew the modulator from the transmission with channel lock pliers or a thin one-inch wrench.

The vacuum modulator can be checked with a vacuum source for leakage. However, leakage normally results in transmission oil pull-over and results in oil smoky exhaust and continually low transmission oil level. No repairs are possible on the modulator; replace with new unit.

When installing, center the gasket in place with vaseline and hold it centered during installation to prevent an external oil leak.

GOVERNOR

Governor is accessible from beneath the vehicle and is mounted on the left side of the transmission. To remove, unscrew lock screw and pull the unit out of the transmission.

The only part replaceable is the driven gear. Drive out the roll pin with a punch and pull out the gear. Drill a new hole in the governor 90 degrees from the original; then insert a new gear and roll pin.

Fig. 5 Case-to-cable installation

Fig. 7 Removing valve body

When installing, use a new O-ring seal on the governor. Then insert the governor in the transmission with a slight twist to engage the gear teeth.

VALVE BODY & LOW SERVO

Removal

1. Drain oil pan and disconnect throttle valve rods from TV lever on transmission.
2. Remove oil pan and oil pick-up pipe.
3. Make an improvised sheet metal strap, Fig. 7, and loosely install with one pan bolt.
4. Remove bolts securing valve body to transmission, tap valve body lightly with a soft hammer to loosen from its dowels in transmission case, then carefully lower the valve body about 1/16", rotate improvised strap into place so it spans the servo piston hub and secure strap with pan bolt. This eliminates possibility of servo piston slipping down out of its bore and the loss of low band engagement with its apply components.
5. To remove the low servo piston, pull downward on the hub of the piston shaft with a screwdriver. *Do not remove piston in vehicle unless low band screw is first tightened fully.*

Valve Body Repairs

Referring to Fig. 8, disassemble valve body as follows:

1. If installed, remove manual valve.
2. Remove screws and separate modulator valve body from main valve body. *Modulator body should be held during removal of screws as it is under spring pressure from the pressure regulator valve spring.*
3. Remove pressure regulator valve spring retainer, spring, and pressure regulator valve.
4. From the modulator body, remove rear pump priming ball and the front and rear pump check valves and springs. Also remove modulator valve.
5. To remove line pressure limiting valve, drive roll pin from modulator valve body with a punch, then remove line pressure limiting valve

Fig. 8 Valve body components

spring and valve from their bore in the modulator body.

6. Remove screws and separate the transfer plate and gasket from the main valve body.
7. To remove the low drive shift valve components, remove retainer ring, then release the pressure and remove low drive regulator valve sleeve, regulator valve, spring seat and inner and outer springs. Lightly tap main valve body with a plastic mallet to remove the low drive shift valve from its bore.
8. To remove the TV valve components, remove retaining pin by wedging a thin screwdriver between its head and the surface of the main valve body, then remove detent valve assembly and throttle valve spring. Complete disassembly of the throttle body by removing the "E" ring from the throttle valve, then remove throttle valve from main valve body by tapping valve body with a plastic hammer.

Inspection

A thorough cleaning of all parts in clean solvent is mandatory. Check all valves and their operating bores for burrs or other deformities which could result in valve hang-up.

Assemble

Referring to Fig. 8, complete assembly by reversing the foregoing instructions. Tighten screws to 38-50 *inch lbs.* and check shift cable adjustment as described earlier.

Low Servo Piston Repairs

Disassemble the servo piston by removing the hairpin clip. Remove ring from piston and install it in low servo bore to measure the ring gap which should be .002″ to .012″.

Assemble ring to piston and measure clearance between ring and one wall of piston groove which should be .0005″ to .005″.

Installation

1. Install low servo piston and return spring in transmission bore and engage notch in piston shaft with low band apply strut, loosening low band screw slightly to permit piston ring to seat in case bore.
2. Install valve body in transmission while simultaneously loosening low band screw until it is possible to index valve body on dowels in case. If manual valve is installed, index it with a manual valve lever in case; then secure valve body with 20 bolts to a torque of 9-11 ft. lbs.
3. Install O-ring in valve body and install oil pick-up pipe and secure with screw.
4. Complete installation and adjust low band as outlined previously.

Service Operations, Power Train Removed

All operations which follow must be performed with the power train removed from the vehicle and mounted on the fixture used for its removal.

TRANSMISSION DISASSEMBLE

1. Drain oil and remove 12 bolts securing front pump to case.
2. *If overhaul is being made with the transmission installed on power train, loosen low band adjusting screw jam nut and fully tighten the adjusting screw. This will prevent the case components from being pulled out when front pump is removed, Fig. 9.*
3. Remove front pump cover and pull out pump shaft, Fig. 10. Remove front pump body from case, using care not to drop pump gears. Remove pump gasket.
4. Loosen low band adjusting screw and remove low band and related parts, Fig. 11.
5. Remove clutch drum, Fig. 12. *If operations are being performed with the transmission attached to the power train, care should be taken not to disengage the ring gear from the reverse clutch face plates unless replacement of either the ring gear or reverse plates is anticipated. Engagement of the reverse plates and ring gear in the horizontal position is generally difficult and should not be attempted unnecessarily.*
6. Remove planet carrier from ring gear and remove turbine shaft. On disassemblies made with the transmission separated from the axle, the turbine shaft is removed with the separation of the two units.

NOTE—The foregoing concludes the extent of disassembly which should be attempted with the transmission assembled to the power train. Although the reverse clutch plates are accessible without further tear-down, any failure of these plates can reasonably be assumed to be caused by malfunction of the reverse clutch, access to which requires the removal of the transmission from the power train. The remaining disassembly operations can only be performed with the transmission separated from the power train.

Fig. 9 Removing front pump with slide hammers

Fig. 10 Removing front pump drive shaft

Fig. 11 Low band components

7. Remove ring gear, Fig. 13.
8. Remove clip, Fig. 14, mounted on the thick reverse reaction plate between the ends of the reverse clutch snap ring. Then remove snap ring.
9. Remove the thick reverse reaction plate, the three faced plates and the thin steel plates.
10. Remove rear pump and reverse piston mounting bolts, which are accessible from the rear (differential carrier side) of transmission case.
11. Remove rear pump and reverse piston by pulling forward with a twisting action.
12. Remove rear pump wear plate from rear of case.

INSPECTION & REPAIRS

1. Referring to Fig. 15, wash all parts with solvent and dry with compressed air. Handle transmission case carefully to avoid damaging finished surfaces as such damage could result in oil leakage.
2. Inspect all mating surfaces of the transmission case for nicks and other damage and repair as required. Be especially careful to check the area around the manual shift cable as over-tightening the cable nut could possibly crack the case at this point. Check case bores for wear and grooves.
3. Inspect condition of ring gear teeth and splines.
4. Inspect governor drive gear, splines and teeth for wear.
5. Inspect rear pump wear plate for wear and abrasion.
6. If clutch drive plate facings are worn or show signs of intensive heat, replace plates. Reaction (steel) plates, unless external tangs are peened or damaged, are generally serviceable even after failure of drive plates.
7. In the valve body area of the transmission case, check that the priming ball is retained by its wire retainer and see that the ball and its seat in the case is not deformed. Repair any seat deformation and if ball is damaged, replace it.
8. Check manual valve and TV valve linkage. If damaged replace as required.
9. If necessary, remove valve body oil pick-up tube and clean screen. Also check that the O-ring seal used between the pick-up and valve body is in good condition.
10. Inspect condition of low band. If it shows signs of excessive heat, brittleness of facing can be expected and the band should be replaced.
11. Individual inspection and repair procedures are covered in the following text. The seven bushings used in the transmission are indicated in Fig. 15 together with the applicable bushing installer.

Front Pump

1. Wash all parts and blow out oil passages.
2. If inspection shows that pump gears are serviceable, install gears and check:

Fig. 12 Removing clutch drum

Fig. 13 Removing ring gear

Fig. 14 Reverse clutch pack retainer ring and clip

a. Clearance between OD of driven gear and body should be .0025-.005″.
b. Clearance between driven gear and crescent should be .003-.009″.
c. With scale and feeler gauge check gear end clearance, which should be .0005-.0015″.
d. Inspect pump drive gear teeth for interference between tops of teeth and crescent in pump.

6. Replace gasket and square cut seal ring in OD of front pump cover. Also check condition of cast iron seal rings on pump body hub.
7. Check condition of front pump body bushing and replace if necessary.

Fig. 15 Powerglide transmission

Clutch Drum

1. Referring to Fig. 16, disassemble clutch drum as picture suggests.
2. Inspect clutch drum band surface for excessive scoring or burning. Also check drum bushing for scoring or excessive wear.
3. Check steel ball in clutch drum that acts as a relief valve. Be sure that it is free to move in the hole and that the orifice leading to the front of the drum is open. If the ball is loose enough to rattle, replace clutch drum as an assembly. Replacement or staking the ball should not be attempted.
4. Check fit of clutch flange in drum slots. There should be no appreciable radial play between these two parts. Also check low sun gear for nicks or burrs and bushing for wear.
5. Check clutch plates for burning, pitting or metal pick-up. Also check to see that the faced plates are a free fit over clutch hub and that the steel plates are a free fit in clutch flange. Check for excessive wear on friction facing of drive plate teeth. Check condition of clutch hub splines and mating splines on faced plates.
6. Assemble clutch drum in reverse order of disassembly, referring to Figs. 16 and 16A.

Planet Carrier

Wash planet carrier in cleaning solvent, blow out all oil passages and air dry. Inspect planet pinions for nicks or other tooth damage. Check end clearance of planet gears; clearance should be .005″ to .035″. Check sun gear teeth for damage, also check sun gear thrust washer for damage. Inspect planet carrier splines for nicks or other damage. Also check pinion shaft ends for proper staking.

If during inspection, parts show excessive wear, they should be replaced. Fig. 17 is an exploded view of the assembly.

Turbine Shaft

Check the shaft for nicks and cracks and check the splined areas for wear. Check that the two lube holes are open. Also inspect the bushings and replace if necessary.

Pump Shaft

Check the splines at the converter end of the shaft for wear or damage. Inspect the bronze faced drive lugs for peened edges and wear of its splined connection to the shaft by twisting to check for looseness. Be especially careful to check that the drive hub is tightly retained by the snap ring. If bronze hub is worn, remove top snap ring and replace hub.

Rear Pump and Reverse Piston

1. Referring to Fig. 18, disassemble as picture suggests. The tools shown in Fig. 19, together with a press aids in disassembly.
2. Check fit of pump gears as described for the front pump. Fits and tolerances are identical.
3. Inspect pump body for leaks and scoring. Check hub of pump body for smoothness. Any burrs on the surface would cause leakage and

Fig. 16 Installing clutch drum plates

could result in a jammed reverse piston.

4. Check for broken return springs and make a comparative check of spring heights by standing all springs in a row. If appreciable variance of spring height is noted, replace springs.
5. Check condition of rear pump body bushing and replace if necessary.

Converter

It is not necessary to drain the converter as it is welded and no internal repairs can be made.

Check the starter gear for worn or broken teeth and for broken welds at its attachment to the converter assembly. If starter gear is undamaged but welds are loose or broken, reweld as required.

Check converter seams for stress or breaks and either replace converter or repair welds as required. If welds are repaired, keep added material to a minimum by carefully chipping off all scale and filing away any unnecessary weld to obtain converter balance as close to original as possible. Replace the converter if roughness due to unbalance is noted after reassembly to engine. Check converter bushing for wear and replace if necessary.

TRANSMISSION ASSEMBLE

The following steps apply only if the transmission is separated from the Power Train.

1. Install two improvised guide pins in rear pump bolt holes. Install rear pump wear plate on guide pins, using a small amount of vaseline to hold plate in place.
2. Insert rear pump and reverse piston. Then insert a length (½" to ¾" wide) of .010-.015" shim stock between piston outer seal and case. With rear of case downward, running the shim stock around the entire diameter of the seal will seat the seal quickly. Remove guide pins and install rear pump mounting bolts, torquing them to 9-11 ft. lbs.
3. Install reverse clutch drive and reaction plates alternately starting with a steel plate, and finishing with a faced plate. The notched lug in each steel plate is installed so it is at the top of the groove at the 4 o'clock position in the case. Then install the thick reaction plate; it has a square "dimple" on its lug which engages the 4 o'clock case groove.
4. Install reverse clutch retainer ring in such a manner so that the open ends of the ring are at the 12 o'clock position; then install retainer clip (Fig. 14) on thick reaction plate between ends of snap ring.
5. With rear of transmission case downward, align internal lands and grooves of reverse face plates.
6. Engage ring gear to reverse drive plates, Fig. 13. Engagement must be made by feel while jiggling the drive plates laterally.
7. *On assemblies being performed with the transmission installed on the Power Train, Install the turbine shaft at this point. Be sure to fully engage splines of turbine shaft to those in converter turbine.*
8. Install planetary unit with a slight twist to engage planet gears with ring gear. Be sure to engage the two rear pump drive lugs on planet hub with grooves in rear pump drive gear.
9. Install thrust washer on captive input sun gear in planetary gear set with flange of thrust washer toward front of transmission. If necessary, apply a small amount of vaseline to keep thrust washer centered, especially if the work is being performed with the transmission assembled to the Power Train.
10. Install clutch drum assembly, using a slight twist to engage low sun

Fig. 17 Planet carrier assembly

10. Thrust washer
11. Planet carrier

Fig. 16A Clutch drum and component parts

Fig. 18 Rear pump and reverse piston

Fig. 19 Removing reverse piston return spring retainer

gear to planet gears in gear set.

11. If assembly is being performed with transmission removed from Power Train, turn transmission to a horizontal position. Then install low band and its component parts, Fig. 20. *When the linkage is all installed, snugly tighten the low band adjusting screw to prevent struts from falling out of place.* Then jiggle clutch drum slightly to center band and linkage.

Front Selective Thrust Washer Determination

At this point, prior to the installation of the front pump when overhauling the transmission while assembled to the Power Train, the thrust washer selection must be determined with the tool shown in Fig. 21 as described below. *The use of this tool and the following procedure is absolutely limited to overhauls performed while the transmission is assembled to the differential carrier. At this point, during overhauls with the transmission separated from the differential carrier, install the original (unless necessary to replace) thrust washer on the front pump hub without gauging, and complete transmission assembly. Final end play adjustment would then be made at the rear (governor gear) as described in the Power Train Section.*

Insert pilot of tool into bore of clutch drum and secure with two front pump mounting bolts. Tighten bolts fully to compress pilot spring. See that the plunger is fully seated. Then observe plunger action and select thrust washer as instructed in Fig. 21. Remove tool and install thrust washer selected on front pump hub.

Final Assembly

1. Install front pump body with new gasket, being careful not to break cast iron oil ring on pump hub when they are indexed to clutch drum.
2. Install front pump drive shaft, Fig. 10. Use care when inserting shaft not to damage bushings in transmission.
3. Install a new square cut seal ring in front pump cover; then position pump cover. Dip bolt heads in oil impervious sealer and install bolts loosely. Tighten outer bolts in a criss-cross pattern to 18-20 ft. lbs. Then tighten five inner bolts to the same torque. By using this sequence, the chance of cocking the pump which would bind the pump hub to the pump shaft is avoided.
4. Adjust the low band by first tightening the adjusting screw until it bottoms; then back off four full turns exactly. Holding adjusting screw and tighten lock nut.

TROUBLE SHOOTING

The use of pressure checks for diagnosis of Corvair Powerglide malfunctions is not recommended at this time; therefore pressure test data are not provided.

No Drive In Any Selector Position; Cannot Load Engine

1. Low oil level.
2. Clogged oil pipe screen.
3. Broken or disconnected manual valve cable.
4. Front pump defective.
5. Front pump shaft disengaged at either converter or pump gear.
6. Front pump priming ball not seating.
7. Defective pressure regulator valve.
8. Defective line pressure limit valve.
9. Rear pump check valve and rear pump priming ball not seating. Both must occur for possible malfunction.

Engine Speed Flares On Standstill Starts But Acceleration Lags

Low band partially applied due to any of the following:

1. Low oil level.
2. Clogged pick-up pipe screen.
3. Improper band adjustment.
4. Servo piston apply passage blocked.
5. Servo piston ring broken or leaking.
6. Band facing worn.
7. Low band apply linkage disengaged or broken.
8. Converter stator not holding (rare).

Engine Speed Flares On Upshift

Fig. 20 Installing low band components

Fig. 21 Gauging clutch drum thrust washer with J-5371. Flush or above use .050" thrust washer. If below flush use .076" thrust washer

1. Low oil level.
2. Clogged oil screen or pipe.
3. High clutch partially applied (blocked feed orifice).
4. Clutch plates worn.
5. Clutch seals leak.
6. Clutch piston hung up.
7. Clutch drum relief ball not seating.
8. Vacuum modulator hose collapsed.

Transmission Will Not Upshift

Low band not releasing, probably due to:

1. Stuck low-drive valve.
2. Defective governor.
3. No rear pump output such as stuck priming ball, drive pins not engaged, or defective pump.
4. TV valve stuck or maladjusted.
5. Maladjusted manual valve lever.

Upshifts Harsh

1. Incorrect carburetor-to-transmission TV rod adjustment.
2. Improper low band adjustment.
3. Vacuum modulator hose broken or disconnected.
4. Vacuum modulator diaphragm leaks.
5. Vacuum modulator valve stuck.
6. Hydraulic modulator valve stuck.

Closed Throttle (Coast) Downshifts Harsh

1. Improper low band adjustment.
2. Vacuum modulator hose disconnected or broken.
3. Vacuum modulator diaphragm ruptured.
4. Vacuum modulator valve stuck.
5. Engine idle speed too high.
6. Sticking valves in valve body (pressure regulator or hydraulic modulator valves).

Car Creeps In Neutral

1. Incorrect manual valve lever adjustment.
2. High clutch or low band not released.

No Drive In Reverse

1. Manual valve lever improperly adjusted.
2. Cable linkage adjustment.
3. Reverse clutch piston stuck.
4. Reverse clutch plates worn out.

5. Reverse clutch leaking excessively.
6. Blocked reverse clutch apply orifice.

Improper Shift Points

1. Incorrectly adjusted carburetor-to-transmission linkage.
2. Incorrectly adjusted TV valve.
3. Governor defective.
4. Rear pump priming ball stuck.

Oil Forced Out of Filler Tube

1. Oil level too high causing planet carrier to run in oil and cause foam.
2. Oil pick-up pipe split or not sealed.

Unable To Push Start

1. Rear pump drive gear not engaged with drive pins on planet carrier hub.
2. Rear pump defective.
3. Rear pump priming ball not seating.

TRANSMISSION SHIFT POINT

Upshifts	M.P.H.
Minimum throttle	10-12½
Full throttle	41-47
Part throttle	34-41

Downshifts	M.P.H.
Closed throttle	8-12
Full throttle	38-44
Part throttle	23-30
Manual low	41-46

Rear Axle and Brake Section

AXLE DESCRIPTION

The Corvair rear axle is of the straddle-mounted hypoid type which embodies a differential carrier mounted rigidly to the engine no rear axle housing is used, Figs. 1 and 2. Independently suspended axle shafts are attached to universal joints which, in turn, are splined into the differential side gears.

A hollow shaft is used with the drive pinion to permit passage of the engine output shaft forward to the transmission. To permit the axial hole in the pinion shaft, the drive pinion and gear are two pieces coupled together. The drive pinion shaft is directly connected to the transmission output member. Preloaded tapered roller bearings support the drive pinion at fore and aft locations in the differential carrier. The ring gear is bolted to the differential case which is mounted on preloaded tapered roller bearings on each side of the differential carrier.

Components of the differential assembly are conventional with the exception of the side gears which have integral elongated splined hubs which project to the outboard extremity of the differential case and cover to receive the axle shaft universal joints.

Fig. 1 Three speed transmission rear axle

AXLE SHAFT, BEARING & U-JOINT

Removal

1. Remove wheel and brake drum.
2. Unfasten bearing retainer from backing plate (four nuts accessible through hole in axle shaft flange).
3. Pull backing plate outward slightly then push it back onto the control arm studs to break away from the bearing retainer. The axle shaft can now be pulled outward sufficiently to free the U-joint splines from the differential side gears.
4. Remove U-joint from axle shaft (4 nuts from U-bolts).
5. Remove yoke from axle shaft.

Axle Shaft Bearings, Replace

1. Place axle shaft in a press with puller plate below the puller ring, Figs. 3, 3A.
2. Remove oil deflector, bearing and puller ring.
3. To install, place a new puller ring, bearing and oil deflector on axle shaft. *To prevent damaging bearing during installation of the new parts, place the old puller ring with its flat side against the bearing inner race and then press the puller ring and bearing onto the axle shaft.*
4. Remove old puller ring and install oil deflector.

Installation, Fig. 4

1. Insert axle shaft through lower control arm and install U-joint yoke on splines of axle shaft. It may be necessary to lightly tap yoke onto splines if original pieces are being installed. *When assembling new pieces for the first time, it is good practice to assemble and disassemble the yoke to the axle shaft with a press to ease the assembly of the*

Fig. 2 Powerglide transmission rear axle

pieces in the vehicle.

2. Secure U-joint flange to axle shaft.
3. Attach U-joint to yoke on shaft with U-bolts.
4. With bearing retainer holes lined up with control arm studs, insert U-joint splines through seals in side bearing adjusting sleeves and index with side gear splines.
5. Secure bearing retainer to brake backing (4 nuts) via access hole in axle shaft flange.
6. Position brake drum control arm studs and secure wheel and drum.

Fig. 3 Axle shaft bearings. 1961

SIDE BEARING SLEEVE SEAL

The side bearing adjusting sleeve seal may be replaced while installed in the vehicle. Remove the U-bolt from the side bearing adjusting sleeve. Pry out the seal, then install the new seal using any flat object as a driver as the seal mounts flush. *Seal lips must be inward.*

DIFFERENTIAL CARRIER

For removal and installation of the differential carrier, refer to the *Power Train Section.*

Disassemble Carrier

1. Loosen lock tab and remove speedometer driven gear.
2. Remove differential carrier cover.
3. Remove side gear adjusting sleeves, Fig. 5.
4. Remove pinion adjusting sleeve, Fig. 6
5. Remove pinion drive gear with bearings attached, Fig. 7.
6. Remove differential from carrier by shifting differential to one side of carrier and then turning 90 degrees in order to remove via the cover hole in carrier.

Inspection

1. Inspect all bearing cups, races and rollers for damage and wear, especially large end of rollers as this is where wear is most evident on taper roller bearings. *The rear axle pinion bearings are of the preloaded type, and the natural wear pattern is a slightly frosted condition with occasional slight scratches on races and rollers. This does not indicate a defective beaing.*
2. On Powerglide axles, inspect oil seal in stator support and at converter hub for evidence of wear or damage.
3. Inspect pinion splines for evidence of excessive wear.
4. Inspect ring gear and pinion teeth for scoring, chipping or cracking.
5. Check fit of differential side gears in case.
6. Check fit of side gear and U-joint shaft splines.
7. Inspect differential pinion shaft for scoring or evidence of excessive wear.
8. Inspect differential carrier for cracks or cross threads.

AXLE REPAIRS

For Three Speed and Powerglide Axles

Note—Repairs required on three speed axles only, and those for Powerglide axles only are outlined further on. Refer to Fig. 8 for relationship of parts.

Pinion and Bearing, Replace

When it becomes necessary to replace pinion bearings and/or ring gear and drive pinion, it is necessary to re-establish the pinion mounting distance.

Pinion bearings may be removed with the aid of a press. It will be noted that a shim or shims are used between the pinion rear bearing and pinion. To determine the shim thickness to be used when installing new parts special gauges are required, Fig. 9. Lacking this equipment, check the ring gear contact pattern as shown in Fig. 10. To do this the differential carrier must be assembled. If a change is indicated, disassemble the parts and change the shimming as required to obtain the proper tooth contact pattern. Shims are available in thicknesses of .006, .009, .012, .015 and .018".

Fig. 3A Axle shaft bearings. 1962-63

Fig. 5 Removing side bearing adjusting sleeve

Pinion Front Bearing Race

Remove the old race with a punch. On Powerglide models it is necessary to remove the seal. Install a new race in the pinion adjusting sleeve using a suitable driver to push the race in place. Install a new seal on Powerglide units.

Side Bearing Adjusting Sleeve Bearing Race

1. Punch mark the side bearing adjusting sleeve at two places $\frac{9}{16}''$ outboard from the seal bore 180° apart, Fig. 11.
2. Using a $\frac{3}{16}''$ or smaller drill, drill through the adjusting sleeve at the punch mark locations until the drill is stopped by the bearing race.
3. Drive out the bearing race with a small pin punch.
4. Install a new bearing race in the sleeve with a suitable flat plate as a driver until the bearing race is flush.
5. Seal the drilled holes by using lead balls of at least .225″ diameter, Fig. 12. Balls of this type are commercially available for carburetor repair kits.

Differential Overhaul

Disassemble the differential as suggested by Fig. 13. To remove the differential pinions after the case has been separated, drive out the roll pin securing the differential pinion shaft to the case. *Before separating the differential case halves, punch mark the rim of both halves so that they may be attached in the original position, Fig. 14.* When securing the ring gear to the case, tighten all bolts to a torque of 40-60 ft. lbs. in a criss-cross pattern.

Fig. 6 Removing pinion adjusting sleeve

REPAIRS ON 3 SPEED TRANS. AXLES ONLY

Clutch Release Bearing Shaft Seal

Fig. 4 Axle shaft components

Remove split ring and old seal from clutch release bearing shaft by prying out with a punch. Install the new seal, open side inward, using a suitable socket (¾″) and socket extension. Drive seal until it bottoms, then install split ring in clutch release bearing shaft.

Clutch Release Bearing Shaft and/or Pinion Bearing Rear Race

1. Place differential carrier in arbor press and press out shaft and race.
2. If a new shaft is being installed, first install the inner seal. Install a new seal ring in groove on outer diameter of bearing shaft and lubricate with vaseline.
3. Support differential carrier only on boss at clutch release bearing location with a suitable cylinder; then place bearing race on shaft and press both into differential carrier. Press until cup is flush with adjacent surface inside carrier.

REPAIRS ON POWERGLIDE AXLES ONLY

Pinion Shaft Front Oil Seal and/or Converter Hub Oil Seal

The pinion shaft front oil seal and the converter hub oil seal are located diametrically opposite fore and aft, respectively, in the differential carrier.

Remove the oil seal by prying out with a punch or similar tool. Coat outer diameter of new seal with a non-hardening sealer and install seal. The converter hub seal is mounted flush. A special driver is available to install the pinion seal. A stop is provided on this driver which insures the seal being installed to the proper depth. This same driver (J-8340) is also used to drive the converter hub seal.

Pinion Shaft Rear Oil Seal

Drive out the old seal with a pin punch inserted through access hole in stator shaft. Install new seal as shown in Fig. 15 until it bottoms.

Pinion Shaft Bushing

Remove old bushing from inside diameter of pinion shaft using a chisel or other suitable tool. Use care not to damage the bushing mating surfaces in pinion shaft during removal.

Install new bushing with a suitable driver. Special tool J-8333 is available for this operation; it has a stop provided thereon to press the bushing to the proper depth.

Fig. 7 Removing pinion from carrier

Fig. 8 Differential carrier assembly

Fig. 9 Pinion depth shim selection gauges

Fig. 10 Ring gear tooth contact patterns

Fig. 11 Drilling side bearing adjusting sleeves for bearing race removal

Stator Shaft and/or Pinion Rear Bearing Race

1. Remove stator shaft and pinion bearing cup from carrier by placing carrier in a press and pressing downward on end of stator shaft. Replace parts removed.
2. Install seal ring in groove on outside diameter of stator shaft and lubri-

Fig. 12 Sealing drilled holes in adjusting sleeve with lead balls

cate with vaseline. *Outer diameter seal is not used on later production stator shafts.*

3. If a new stator shaft is being installed, it will be necessary to install a new pinion rear oil seal as previously described.
4. Align notch in stator shaft, Fig. 15, with drain back passage boss in differential carrier. Place bearing race on stator shaft and press race and shaft into housing, Fig. 16. *Carrier must be supported only at stator shaft boss for this operation.*

ASSEMBLE DIFFERENTIAL CARRIER

1. Referring to Fig. 8, insert differential into carrier with side bearing cones installed on differential hubs.
2. While differential is loose in carrier, insert pinion into carrier through cover hole. Then engage pinion with ring gear and carefully position pinion rear bearing in race. On Powerglide models, care must be used not to damage seal at this location when pinion is installed.
3. Install new O-ring seals in side bearing adjusting sleeves. Coat adjusting sleeve threads with a non-hardening pipe thread compound. Loosely install sleeves in carrier with side bearings positioned in sleeves.
4. On Powerglide models, install a new O-ring seal in pinion adjusting sleeve. Position pinion so that its front bearing will pick up the bearing race in sleeve and loosely install sleeve in carrier. Use care not to damage seal lips when inserting pinion shaft over adjusting sleeve.
5. Tighten both side bearing adjusting sleeves and pinion adjusting sleeve to the point of contact between bearings and races. At this point, there should be no preload on any of the bearings and ring gear and pinion backlash should be just enough so that the pinion and differential can be rotated easily and smoothly. The assembly is now ready for ring gear and pinion adjustment. *This adjustment, as well as checking ring gear and pinion backlash and other differential case operations is described in the Rear Axles Chapter.* Also refer to Fig. 10.

Fig. 13 Differential assembly

Fig. 15 Installing pinion rear oil seal in stator shaft

Fig. 16 Installing stator shaft and pinion rear bearing race

BRAKE ADJUSTMENT
1961-62

Hydraulic brake adjustment is confined to a single operation on each brake assembly. A spring snap cover plate is pried from the back of the brake backing plate to gain access to the star wheel adjuster. With all wheels raised off the floor, adjust as follows:

1. On rear brakes loosen check nut at parking brake cable equalizer to remove tension from brake cable. *If cable has been adjusted too short, rear brake shoes will be forced away from the anchor pins in brake release position, making correct shoe adjustment impossible.*

2. Expand brake shoes by turning star wheel adjuster with a screwdriver or special brake tool until a heavy uniform drag is felt on the brake drum. Moving outer end of tool upward expands the shoes.
3. Turn adjusting screw back 7 notches on each wheel.
4. To adjust brake cable, pull parking lever up 4 notches from released position. Then adjust equalizer nuts so that a heavy drag is felt when rear wheels are rotated. Tighten equalizer nuts and check adjustment. With hand brake released, no drag should be felt when rear wheels are rotated.

1963 Self-Adjusting Brake

Brake shoe adjustment takes place when brakes are applied with a firm pedal effort while vehicle is backing up. Applying the brakes moves the actuator which turns the star wheel and lengthens the adjusting screw assembly. This action adjusts the shoes until clearance between lining and drum is within proper limits. When the brakes are relined, an initial adjustment is made as follows:

1. With brake drum off disengage actuator from star wheel and rotate star wheel by spinning or turning with a screwdriver.
2. Using the brake drum as an adjustment fixture, turn star wheel until drum slides over brake shoes with a slight drag.
3. Turn star wheel 1¼ turns to retract brake shoes. This will allow sufficient lining-to-drum clearance so final adjustment can later be made.
4. Install drum and wheel.
5. Make final adjustment by driving and stopping the vehicle in reverse until satisfactory brake pedal height is obtained.

MASTER CYLINDER, REPLACE

1. To remove, disconnect hydraulic line from outlet end of cylinder.
2. Remove pedal return spring.
3. Unfasten master cylinder from dash wall and remove cylinder-pedal assembly.
4. When installed, fill master cylinder reservoir and bleed air from system.

Suspension and Steering Section

FRONT WHEEL BEARINGS, ADJUST

1. Jack up vehicle and remove hub cap and dust cap.
2. Remove cotter pin and tighten spindle nut to 15 ft-lbs torque while rotating wheel.
3. Back off adjusting nut one flat and insert cotter pin.
4. If slot and cotter pin hole do not align, back off adjusting nut an additional ½ flat or less as required to insert cotter pin.
5. Spin wheel to make sure it rolls freely. Secure cotter pin.

CASTER & CAMBER, ADJUST

Caster and camber adjustments are made by means of shims between the upper control arm inner support shaft and the support bracket attached to the frame side rail. Shims may be changed at either the front or rear of the shaft to change caster or at both points equally to change camber.

The addition of shims at the front bolt or removal of shims at the rear bolt will decrease positive caster. A $\frac{1}{32}$" shim difference (one shim) will change caster ¼°. Adding shims at both front and rear of support shaft will decrease positive camber. A $\frac{1}{32}$" shim will move camber 1/6°.

The adjustment procedure is to loosen the upper support shaft-to-bracket bolts, add or remove shims as required and retighten bolts.

FRONT WHEEL TOE-IN

1. Set steering gear on high point, with "saw cut" in steering shaft coupling at 6 o'clock position and steering wheel positioned for straight ahead driving.
2. Loosen clamp bolt at each end of each tie rod individually and adjust toe-in to specifications. Tighten clamp bolts and remove equpment.

REAR WHEEL TOE-IN

Due to the design of this independently sprung rear axle and suspension, it will be necessary to check and adjust rear wheel toe-in. *If drive on type equipment is used, reverse the vehicle and back it into position. Toe-in will be read as toe-out when vehicle is backwards because readings will be taken from the rear of the tires rather than the front. A tram may also be used in a similar procedure as that used on the front wheels except both sides will be adjusted at the same time. It must be pointed out, however, that since the wheels are adjusted by adding or removing shims at the front edge of the transmission, both wheels are adjusted at the same time.*

A $\frac{1}{16}$" shim added to each side will increase toe-in. Removal of a $\frac{1}{16}$" shim from each side will decrease toe-in. Shims must be added or removed in pairs so that there is always the same number at each point.

Toe-in should be ¼" to ½" per wheel. Due to manufacturing tolerances and parts "stack-up" it is possible to have toe-out on one wheel and toe-in on the opposite wheel. In this case, adjust the suspension to bring the wheel with the toe-out as close to specifications as possible but not letting the opposite wheel go out of specifications. For example, if one wheel toes-out by ¼", then the opposite wheel must toe in enough to give 0" to ¼" overall toe-in.

Rear Wheel Camber

Rear wheel camber should be ¾° positive (plus or minus ½°). There is no provision for adjustment of this item and it is provided as a checking specification only.

If camber is not within limits, either the crossmember is out of alignment with the body or has become distorted due to collision, etc., or else the control arm has become distorted, bent, etc.

FRONT END REPAIRS

Shock Absorber, Replace

1. With vehicle supported and front end hanging free, remove upper attaching nut, cup washer and grommet.
2. Remove two lower attaching bolts.
3. Withdraw shock absorber through lower control arm.
4. Reverse above procedure to install, extending shock absorber shaft to its full length to facilitate installation.

Upper Ball Joint

The upper ball joint is inspected for wear by checking the torque required to rotate the ball stud in the assembly. Support vehicle at outer end of lower control arm and remove wheel. Remove nut from upper control arm ball stud. Remove stud from steering knuckle. Raise control arm to clear knuckle and install a nut on the stud and measure torque required to turn stud. This should be a minimum of 2 ft. lbs. If excessive wear is indicated in upper joint, both upper and lower joints should be replaced. If a tight joint is suspected, 15 ft. lbs. is the maximum allowable torque with the joint well lubricated.

Lower Ball Joint

The lower ball joint is a loose fit in the assembly when not connected to the steering knuckle. If inspection reveals that the upper joints are serviceable, inspect lower ball joints for excessive wear as follows:

1. With wheels resting on floor, measure distance from top of lube fitting to bottom of ball stud. Record dimensions for each side.
2. Now jack up car under outer end

Fig. 1 Rear axle positioning for spring removal

of each lower control arm and take same measurement.

3. If the difference in dimensions on either side is greater than $\frac{3}{32}''$, the joint is excessively worn and both lower joints should be replaced. Another indication of lower joint wear is when difficulty is experienced when lubricating the joint. If the metal liner has worn to the point where the lubrication grooves in the liner have worn away, then abnormal pressure is required to force lubricant through the joint. This is another reason for replacing both lower joints.

To test whether or not the stud is loose in the knuckle, remove the cotter pin and prick punch a mark on the nut and stud to identify relative location later. Then tighten nut to original position and observe torque reading. If less than 45 ft. lbs., stud may have been loose in the knuckle and both lower joints should be replaced.

REAR SUSPENSION REPAIRS

Shock Absorber, Replace

The attachment of the rear shock absorber is identical to the mounting of the front suspension. However, the rear shock absorber holds all of the rear spring compression. For this reason, the weight of the vehicle must be resting on the tires.

Place the car on a drive-on type hoist, frame contact hoist or place jack stands under the body at each side rail, just forward of the rear wheel openings. The body should be raised high enough so that the wheels hang free and a floor jack can be placed under the tire. With a second jack, raise tire so that it is in normal position. This will allow shock absorber to be removed without interfering with the floor.

Coil Spring, Replace

1. Raise vehicle by body side rails so that control arms may swing free. Vehicle must be raised enough to allow a rolling floor jack to be placed under brake drum.
2. Loosen control arm cross shaft bolts (in ends of shaft). Remove bolt that holds brake hose bracket to underbody. It may also be necessary to disconnect and plug fuel line and heater fuel supply line (on left side only). Remove wheel. Replace nuts on studs to hold drum in place.
3. Position axle as shown in Fig. 1 to allow axle shaft and control arm to swing down far enough to remove spring.
4. Place rolling jack under brake drum. Raise jack slightly to place a light load on spring. Remove shock absorber.
5. Carefully lower floor jack until spring is free. *Do not remove or lower jack too far as this places too much strain on axle shaft and brake hose.*
6. Reverse above procedure to install and lower vehicle to floor. Bounce rear end several times and tighten cross shaft bolts to a torque of 45-55 ft. lbs.

STEERING GEAR, ADJUST

There are two adjustments to be made on the steering gear which must be performed in the following order:

Worm Bearing Preload

1. Disconnect steering connecting rod from pitman arm.

Fig. 2 Steering gear adjustment points

2. Loosen lash aduster screw, Fig. 2, enough to remove all high spot preload.
3. Rotate steering wheel to end of travel, then turn wheel back one full turn.
4. Hook a spring scale to steering wheel rim and rotate wheel by pulling on spring scale. Pounds pull necessary to keep wheel in motion should be ½ to ¾ lb. If not within this range, adjust as follows:
5. Loosen worm bearing adjuster lock nut and turn adjuster in proper direction to obtain ½ to ¾ lb pull on scale. Turning adjuster to the right increases preload.
6. Tighten lock nut and check adjustment. If there is a wide variation of scale readings or if there is a feeling of roughness while turning steering wheel, gear should be disassembled and inspected for worn or damaged parts.

High Point Preload

1. Rotate steering gear to center of travel.
2. Turn lash adjusting screw into gear case, Fig. 2, until light contact is felt between sector gear and ball nut.
3. Hold adjusting screw in position with screwdriver and tighten lock nut against gear case.
4. With spring scale attached to steering wheel rim, move steering wheel clockwise through high point (¼ turn away from center of gear

Fig. 3 Steering gear

travel) and observe scale reading, which should be 7/8 to 1½ lbs.

5. When adjustment is correct, tighten adjusting screw lock nut and recheck adjustment.

STEERING GEAR, REPLACE

1. Remove bumper and left front outer extension panel.
2. Remove steering connecting rod from pitman arm.
3. Remove steering wheel, turn signal assembly and mast jacket-to-dash clamp.
4. Unfasten steering gear from body rail and remove from vehicle.

STEERING GEAR REPAIRS

1. Referring to Fig. 3, turn pitman shaft adjuster a few turns counterclockwise. This will remove load from worm bearings caused by the close meshing of rack and sector teeth.
2. Turn worm bearing adjuster counterclockwise a few turns.
3. Unfasten and remove side cover and pitman shaft. *If sector does not clear opening in housing easily, turn worm shaft by hand until sector will pass through opening in housing.*
4. Remove worm bearing adjuster, lock nut and lower bearing from housing.
5. Draw worm shaft and nut assembly from housing. Remove upper bearing. *Use care that ball nut does not run down to either end of worm. Damage will be done to ends of ball guides if nut is allowed to rotate until stopped at end of worm.*
6. Unscrew lash adjuster from side cover. Slide adjuster and shim out of slot in end of pitman shaft.
7. If the ball bearing nut is perfectly free with no indication of binding or tightness when rotated on worm, do not disassemble. However, if these conditions exist, remove clamp and draw guide out of nut. Turn nut upside down and rotate worm shaft back and forth until all 36 balls have dropped out of nut. With balls removed, nut can be pulled endwise off worm.
8. Reverse above procedure to assemble the steering gear and adjust as outlined previously. When assembling lash adjuster, place shim in slot in end of sector shaft. Check end clearance which should not exceed .002. For adjusting purposes, shims of four thicknesses (.063, .065, .067 and .069") are available.

Principles of Operation

Diesel engines differ from other internal combustion engines in a number of ways. Compression ratios are higher than in spark ignited engines. The charge taken into the combustion chamber through the intake consists of air only—with no fuel mixture. Injectors receive low pressure fuel from the fuel pump and deliver it into the individual combustion chambers at the right time in equal quantity and proper condition to burn. Ignition of fuel is caused by the heat of the compressed air in the combustion chambers. Figs. 1 and 2 illustrate sectional views of a typical engine, and Figs. 3 to 6 show the operating cycle.

PT FUEL SYSTEM

The principle of the PT (pressure-time) Fuel System is based on the fact that by changing the pressure of a liquid flowing through a pipe you change the amount of liquid coming out of the open end: Increasing the pressure increases the flow or the amount of liquid delivered, and vice versa. In applying this simple principle to the diesel fuel system it was necessary to provide:

1. A fuel pump to draw fuel from the fuel tank and deliver it to individual injectors for each cylinder.
2. A means of controlling the pressure of the fuel being delivered by the fuel pump to the injectors so the individual cylinders would receive the right amount of fuel for the power required of the engine.
3. Fuel passages of the proper size and type so that the fuel will be distributed to all injectors and cylinders with equal pressure under all speed and load conditions.
4. Injectors to receive low pressure fuel from the fuel pump and deliver it into the individual combustion chambers at the right time, in equal quantity and proper condition to burn. Figs. 7, 8 and 9 show the fuel flow through the system.

Fuel Pump

The fuel pump is made up of three main units, the location of which are shown in Fig. 10.

1. A gear pump which draws fuel from the supply tank and delivers it under pressure through the pump and supply lines to the individual injectors.
2. A pressure regulator which limits the pressure of the fuel to the injectors.
3. The governor and throttle which act independently of the pressure regulator to control fuel pressure to the injectors.

The fuel pump is coupled to the compressor or fuel pump drive which is

Fig. 1 Cross section of typical Cummins engine (side view)

Fig. 2 Cross section of typical Cummins engine (end view)

Fig. 7 PT fuel system fuel flow diagram for In-Line engines

driven from the engine gear train. The fuel pump mainshaft turns at engine crankshaft speed, and drives the gear pump, governor and tachometer shaft.

Gear Pump—The gear pump is located at the rear of the fuel pump and it is driven by the mainshaft. This unit consists of a single set of gears to pick up and deliver fuel throughout the fuel system. From the gear pump fuel flows through the filter screen and to the pressure regulator.

Pressure Regulator—The pressure regulator is a by-pass valve to regulate the fuel supplied to the injectors under pressure. On new regulators, some of the by-passed fuel flows back to the suction side of the gear pump and some is dumped into the governor weight carrier cavity, depending upon the speed under which the engine is operating.

Throttle—Fuel for the engine flows past the pressure regulator to the throttle shaft. Idle fuel passes around the shaft to the idle jet in the governor. For operation above idle, fuel passes through the throttling hole in the shaft and enters the governor through the primary jets.

Automotive Type Governor—This is an idling and high speed mechanical governor. Governor action is provided by a system of springs and weights, and it has two functions:

1. It maintains sufficient fuel for idling with the throttle control in idle position.
2. It cuts off fuel above maximum rated rpm.

The idle springs in the governor spring pack position the governor plunger so the idle fuel jet is opened enough to permit passage of fuel to maintain engine idle speed.

During operation between idle and maximum speeds, fuel flows through the governor to the injectors in accord with engine requirements as controlled by the throttle and limited by the pressure regulator. When the engine reaches governed speed, the governor weights move the governor plunger, and fuel passages to the fuel supply manifold are shut off. At the same time another passage opens and dumps the fuel to the supply manifold back into the main pump body. In this manner engine speed is controlled and limited by the governor regardless of throttle position. Fuel leaving the governor travels through the shut-down valve, inlet supply lines and on into the injectors.

Injectors

Fuel circulates through the injector, Fig. 11, at all times except during a short period following injection into the cylinder. From the inlet connection, fuel flows down the inlet passage of the injector, around the injector plunger, between body end and cup, up the drain passage to the drain connections and manifold and back to the supply tank.

As the plunger comes up, the injector feed passage is opened and fuel flows through the metering orifice into the cup. At the same time, fuel flows past the cup and out the drain orifice. The amount of fuel which enters the cup is

Fig. 3 The intake stroke

Fig. 4 The compression stroke

Fig. 5 The power stroke

Fig. 6 The exhaust stroke

Fig. 8 PT fuel system fuel flow diagram for V8-265 (also V6-200) engine

controlled by the fuel pressure against the metering orifice. Fuel pressure is controlled by the fuel pump as previously described.

The plunger during injection comes down until the metering orifice is closed and the fuel in the cup is injected into the cylinder. During the period that the plunger is seated, all fuel flow through that injector ceases, Fig. 12 illustrates the fuel injection cycle.

Adjustable Flow Injectors

New injectors with adjustable flow bodies are being used on all production engines. This type injector contains a larger metering orifice and a selected orifice plug in the inlet passage to regulate proper fuel flow. It is designed to improve fuel distribution between individual cylinders, obtain more uniform manifold pressures on the same model engines; provide engines with torque curves with closer tolerances; improve quality of injectors and balance the flow to closer standards.

THE AIR SYSTEM

The supercharger, Fig. 13, is a gear-force additional air into the combustion chambers so the engine can burn more fuel and develop more horsepower than if it were naturally-aspirated.

SUPERCHARGER

The supercharger, Fig. 13, is a gear-driven air pump which uses rotors to force air into the engine cylinders. The supercharger is driven from the engine crankshaft through a gear train turning at about 1.8 engine speed.

Fig. 10 PT fuel pump with mechanical governor for automotive use

Fig. 9 PT fuel system fuel flow diagram for V8-350 and VT8-430 engines

TURBOCHARGER

The turbocharger consists of a turbine wheel and a centrifugal blower impeller, or compressor wheel, separately encased but mounted on and rotated with a common shaft.

The power to drive the turbine wheel (which in turn drives the compressor) is obtained from the energy of the exhaust gases. The rotating speed of the turbine changes as the energy level of the exhaust gas changes so the engine is supplied with enough air to burn the fuel for its load requirements.

Trouble Shooting Section

The source of most engine troubles can be traced not to one part alone but to the relationship of one part with another. Too often, engines are completely disassembled in search of the cause of a certain complaint and all evidence is destroyed during disassembly operations. Check all the possible causes listed below to be sure you have not missed an easy solution to the problem.

After a mechanical failure has been corrected, be sure to locate and correct the cause of the trouble so that the same trouble will not repeat itself. A complaint of "sticking injector plungers" is corrected by repairing or replacing the faulty injectors, but something *caused* the plungers to stick. The cause may be improper injector adjustments, or more often, water in the fuel.

Most troubles are simple and easily corrected. Examples are "low power" complaints caused by loose throttle linkage or dirty fuel filters, "excessive lube oil consumption" caused by leaking gaskets or connections, etc.

The following text includes some of the most common complaints that may be encountered during the service life of the engine. Not all the answers are given for the correction of the complaints listed, but it is meant to stimulate a train of thought and indicate a work procedure directed to the source of the trouble.

Hard Starting or Failure To Start

1. Restricted air intake.
2. Out of fuel or fuel shut-off closed.
3. Poor quality fuel.
4. Air leaks in suction lines.
5. Restricted fuel lines.
6. Pressure regulator faulty or set wrong.
7. Plugged injector spray holes.
8. Broken fuel pump drive shaft.
9. Scored gear pump fuel or worn gears.
10. Loose injector inlet or drain connection.
11. Long idle periods.
12. Engine due for overhaul.
13. Incorrect valve and injection timing.

Engine Misses

1. Air leaks in suction lines.
2. Restricted fuel lines.
3. Long idle periods.
4. Valve leakage.
5. Injectors need adjustment.

Excessive Smoking At Idling

1. Restricted fuel lines.
2. Plugged injector spray holes.
3. Wrong injector cups.
4. Long idle periods.
5. Gasket blow-by or leakage.
6. Broken or worn piston rings.
7. Engine due for overhaul.
8. Incorrect valve and injection timing.
9. Worn or scored liners or pistons.
10. Injectors need adjustment.

Excessive Smoke Under Load

1. Restricted air intake.
2. High exhaust back pressure.
3. Thin air in hot weather or high altitude.
4. Poor quality fuel.
5. Restricted fuel lines.
6. Plugged injector spray holes.
7. Wrong injector cups.
8. Long idle periods.
9. Engine overloaded.
10. Gasket blow-by or leakage.
11. Broken or worn piston rings.
12. Engine due for overhaul.
13. Incorrect valve and injection timing.
14. Worn or scored liners or pistons.
15. Injectors need adjustment.

Low Power or Loss of Power

1. Restricted air intake.
2. High exhaust back pressure.
3. Thin air in hot weather or high altitude.
4. Poor quality fuel.
5. Air leaks in suction lines.
6. Restricted fuel lines.
7. Pressure regulator faulty or set wrong.
8. Plugged injector spray holes.
9. Scored gear pump (fuel) or worn gears.
10. Wrong injector cups.
11. Throttle linkage.
12. High speed governor set too low.
13. Dirty filters and screens.
14. Long idle periods.
15. Gasket blow-by or leakage.
16. Valve leakage.
17. Broken or worn piston rings.
18. Incorrect crankshaft bearing clearances.
19. Engine due for overhaul.
20. Incorrect valve and injection timing.
21. Worn or scored liners or pistons.
22. Injectors need adjustment.

Cannot Reach Governed R.P.M.

1. Restricted fuel lines.
2. Pressure regulator faulty or set wrong.
3. Throttle linkage.
4. High speed governor set too low.

Throttle Has Flat Spot

1. Pressure regulator faulty or set wrong.

Excessive Fuel Consumption

1. Restricted air intake.
2. High exhaust back pressure.
3. Poor quality fuel.
4. Restricted fuel lines.
5. Pressure regulator faulty or set wrong.
6. External or internal fuel leaks.
7. Plugged injector spray holes.
8. Wrong injector cups.
9. Cracked injector body or cup.
10. Mutilated injector cup "O" ring.
11. Engine overloaded.
12. Incorrect crankshaft bearing clearances.
13. Engine due for overhaul.
14. Misalignment of engine with driven unit.

Poor Deceleration

1. Restricted fuel lines.
2. Incorrectly assembled idle springs.

Erratic Idle Speeds

1. Air leaks in suction lines.
2. Plugged injector spray holes.
3. Incorrectly assembled idle springs.
4. Injectors need adjustment.

Engine Dies

1. Out of fuel or fuel shut-off closed.
2. Poor quality fuel.
3. Broken fuel pump drive shaft.
4. Governor weights assembled incorrectly.
5. Injectors need adjustment.

Surging At Governed R.P.M.

1. Air leaks in suction lines.
2. Injectors need adjustment.

Excessive Lube Oil Consumption

1. External and internal oil leaks.
2. Faulty cylinder oil control.
3. Wrong grade oil for weather conditions.
4. Engine due for overhaul.
5. Worn or scored liners or pistons.

Crankcase Sludge

1. Dirty lube oil strainer.
2. Faulty thermostats.
3. Radiator shutters stuck open.
4. Dirty filters and screens.
5. Long idle periods.
6. Lube oil needs changing.

Oil Dilution

1. External or internal fuel leaks.
2. Loose injector inlet or drain connection.
3. Cracked injector body or cup.
4. Mutilated injector cup "O" ring.
5. External and internal oil leaks.
6. Faulty cylinder oil control.
7. Internal water leaks.
8. Long idle periods.
9. Gasket blow-by or leakage.

Low Lube Oil Pressure

1. Oil suction line restriction.
2. Faulty oil pressure regulator.
3. Incorrect engine bearing clearances.
4. Engine due for overhaul.
5. Damaged main or connecting rod bearings.

Coolant Temperature Too Low

1. Faulty thermostats.
2. Radiator shutters stuck open.

Coolant Temperature Too High

1. High exhaust back pressure.
2. Crankcase out of oil.
3. Insufficient coolant.
4. Worn water pump.
5. Faulty thermostats.
6. Damaged water hose.
7. Loose fan belts.
8. Clogged water passages.
9. Radiator core openings plugged with dirt.
10. Air in cooling system.
11. Exterior water leaks.
12. Insufficient radiator capacity.
13. Engine overloaded.
14. Engine exterior caked with dirt.

Lube Oil Too Hot

1. Insufficient coolant.
2. Worn water pump.
3. Faulty thermostats.
4. Damaged water hose.
5. Loose fan belts.
6. Clogged water passages.
7. Clogged oil cooler.
8. Insufficient radiator capacity.
9. Engine overloaded.
10. Engine exterior caked with dirt.

Piston, Liner & Ring Wear

1. Air leaks between cleaner and engine.
2. Faulty cylinder oil control.
3. Clogged oil passages.
4. Oil suction line restriction.
5. Crankcase out of oil.
6. Dirty filters and screens.
7. Engine overloaded.
8. Lube oil needs changing.
9. Broken or worn piston rings.
10. Engine due for overhaul.
11. Worn or scored liners or pistons.

Wear of Crankshaft Bearings and Journals

1. Air leaks between cleaner and engine.
2. Dirty lube oil strainer.
3. Clogged oil passages.
4. Oil suction line restriction.
5. Crankcase out of oil.
6. Dirty filters and screens.
7. Engine overloaded.
8. Lube oil needs changing.
9. Incorrect bearing clearances.
10. Excessive crankshaft end clearance.
11. Main bearing bore out of alignment.
12. Engine due for overhaul.
13. Damaged main or rod bearings.
14. Misalignment of engine with driven unit.

Worn Valves and Guides

1. Air leaks between cleaner and engine.
2. Dirty lube oil strainer.
3. Clogged oil passages.
4. Oil suction line restriction.
5. Crankcase out of oil.
6. Dirty filters and screens.
7. Engine overloaded.
8. Lube oil needs changing.
9. Valve leakage.
10. Engine due for overhaul.
11. Incorrect valve and injection timing.

Fuel Knocks

1. Poor quality fuel.
2. Air leaks in suction lines.
3. Insufficient coolant.
4. Insufficient radiator capacity.
5. Engine overloaded.
6. Injectors need adjustment.

Mechanical Knocks

1. Insufficient coolant.
2. Engine overloaded.
3. Faulty vibration damper.
4. Unbalanced or loose flywheel.
5. Broken or worn piston rings.
6. Incorrect crankshaft bearing clearances.
7. Engine due for overhaul.
8. Damaged main or rod bearings.
9. Broken tooth in gear train.
10. Loose mounting bolts.
11. Worn or scored liners or pistons.

Gear Train Whine

1. Incorrect bearing clearances.
2. Excessive crankshaft end clearance.
3. Engine due for overhaul.
4. Broken tooth in gear train.
5. Excessive gear backlash.
6. Misalignment of engine with driven unit.

Excessive Engine Vibration

1. Faulty vibration damper.
2. Unbalanced or loose flywheel.
3. Main bearing bore out of alignment.
4. Engine due for overhaul.
5. Misalignment of engine with driven unit.
6. Loose mounting bolts.

Service Adjustments

INJECTORS & VALVES

It is important that injectors and valves be in correct adjustment at all times for the engine to operate properly. The valves control engine breathing and the injectors control fuel delivery to the cylinders.

Proper injector adjustment is also important on PT injectors because they perform the dual function of metering and injection. It takes only one misadjusted injector to make the engine miss. The "miss" may occur in that or another cylinder.

Injectors set too tight deflect the assembly and decrease fuel delivery even though manifold pressure will increase. Loose injector settings increase fuel delivery and promote build-up of carbon. Loose settings are often due to making adjustments on an engine that is too hot.

False injector adjustments may be due to:

1. Carbon inside cup or on end of plunger.
2. Dirty injector seats on cup or in copper sleeve.
3. Binding adjusting screws.
4. Binding rocker levers.
5. Inaccurate torque wrenches.

Timing Mark Alignment

1. Pull compression release lever back and block in open position. This lifts all intake valves and makes it possible to turn crankshaft without working against compression. On engines without compression releases, turn each intake valve adjusting screw down one turn from adjusted position *before* turning the engine.
2. Turn engine in direction of normal rotation until the No. 1 cylinder valve set marks "VS" are lined up as ilustrated in Figs. 1 through 5. In this position both intake and exhaust valves will be closed for No. 1 cylinder.
3. Adjust injector plunger, then the valves for No. 1 cylinder as explained below. Then turn crankshaft in the direction of normal rotation to the next "VS" mark corresponding to the firing order of the engine being serviced. (Firing orders are listed in the *General Specifications* table.)
4. Continue cranking in the direction of rotation and making adjustments until all injectors and valves have been proper adjusted. Two complete revolutions of the crankshaft are needed to set all injector plungers and valves. Injectors and valves can be adjusted for only one cylinder at any one "VS" setting.

Fig. 1 Valve set timing marks. C and J Series engines

Fig. 2 Valve set timing marks. H, NH and NT engines

Injector Plungers, Adjust

Injector plungers on all engines are to be adjusted with an accurate inch-pound torque wrench and a screwdriver adapter. *See the table for proper settings.*

1. Turn adjusting screw down until plunger contacts cup and advance an additional 15° to squeeze oil from cup.
2. Loosen adjusting screw one turn. Then using torque wrench and screwdriver adapter, tighten adjusting screw to the figures shown in the specifications table for the cold setting and tighten lock nut. After all valves and injectors are adjusted and engine has been started and warmed up, adjust the injectors to the warm setting given in table.

Valve Crossheads, Adjust

All four-valve engines have crossheads to operate valves in pairs. These crossheads operate either on a solid or a tubular type guide, Figs. 6 and 7.

1. Loosen crosshead adjusting screw lock nut and back off screw one turn.
2. Use light finger pressure at center of crosshead to hold it in contact with valve stem.
3. Turn down crosshead adjusting screw until it touches valve stem.
4. For new crossheads and guides, advance adjusting screw one-third of a hex (20°) to straighten stem in guide and compensate for slack in threads. With worn crossheads and guides, it may be necessary to advance screw as much as 30° to straighten stem in guide.
5. Hold adjusting screw in this position and tighten lock nut to the torque given in the specifications table.
6. Check clearance between crosshead

and valve spring retainer with a wire gauge. There should be the clearance listed in the specifications table.

Fig. 6 Crosshead with solid guide

Fig. 7 Crosshead with tubular guide

Valves, Adjust

The same engine position used in setting the injectors is used for setting the intake and exhaust valves.

1. While adjusting valves, make sure that the compression release (if so equipped) is in the running position.
2. Loosen lock nut and back off adjusting screw. Insert feeler gauge between rocker lever and top of valve stem or crosshead, and turn screw down until lever just touches gauge. Lock adjusting screw in this position with lock nut, Fig. 8.
3. Always make final valve adjustment after injectors are adjusted and with

Fig. 9 PT fuel pump with automotive type governor. High speed adjustment is made by adding or removing shims under high speed governor spring

engine at operating temperature. Valve clearances are listed in the specifications table.

AUTOMOTIVE TYPE GOVERNOR

High Speed, Adjust

Maximum engine speed is adjusted by adding or removing shims under the high speed governor spring. Normally, this adjustment is made on a fuel pump test stand as the pump is calibrated.

Fig. 10 Idle speed adjustment. Automotive type governor

Idle Speed, Adjust

Warm up engine to operating temperature (140° oil temperature), then shut it off and let it idle. Remove pipe plug from spring pack cover, Fig. 9. The idle adjustment is held in position by a spring clip. Turn spring in to increase or out to decrease the speed, Fig. 10.

Idle speed should be set at 40 to 50 rpm lower than the desired if the adjustment is made with the engine running. With engine running, air collects in the spring pack housing and speed change results when the housing fills with fuel.

Unit Replacement Section

GENERATOR

C, J, H, NH, NT Engines

1. Disconnect wiring leads from generator terminals.
2. On belt-driven units, remove drive belt from generator pulley. *On some C and J applications, No. 1 cylinder injector inlet and drain manifolds may have to be disconnected to remove generator.*
3. Remove capscrews from generator bracket and lift generator and bracket from engine.
4. Remove bracket from generator.

Installation

1. Mount generator to bracket. If bracket does not have the word "Top" cast on it, be sure to mount generator so top generator-to-bracket mounting holes are closer to horizontal centerline of bracket. Failure to do so will place generator oil cup and oil passages out of position.
2. On gear-driven generators, install rubber buffer between generator coupling and drive coupling, and connect the two units. Mount generator and bracket to block.
3. On belt-driven generators, install belt over drive pulley.
4. Connect generator wiring leads to proper terminals.

V6 and V8 Engines

1. Disconnect electrical leads from generator terminals.
2. Loosen generator mounting bolts, remove adjusting link capscrew, lower generator and remove drive belt.
3. Remove generator mounting nuts and lift off generator.
4. Unfasten and remove mounting bracket from engine.

Installation

1. Secure mounting bracket to engine.
2. Install generator on mounting bracket.
3. Install drive belt and raise generator to obtain desired belt tension. After securing with adjusting link capscrews, tighten mounting bolts and nuts.
4. Connect wiring to generator terminals.

STARTING MOTORS

1. Disconnect electrical leads from electric motor or air line from air starter.
2. Unfasten and remove starter and spacer (if used).

Installation

1. Check starter to see if it is the same type as removed. Starters are designed with different type drives that must be used with matching flywheel ring gear.
2. If used, position spacer on starter.
3. Install and secure starter to flywheel housing.
4. Connect wiring to electric starter or air line to air starter.

CORROSION RESISTOR

Many engines are equipped with a corrosion resistor. A single resistor is used on engines having cooling capacities of 20/25 gallons; for larger systems, twin resistors are used.

1. Close shut-off valves in inlet and outlet lines; remove drain plug in resistor housing and drain coolant.
2. Disconnect inlet and outlet lines.
3. Unfasten and remove resistor from engine or mounting bracket.

Installation

1. Secure mounting bracket to engine.
2. Secure resistor to bracket.
3. Attach inlet and outlet lines. The inlet line connects the pressure side of the water pump to the bottom of the resistor. The outlet line connects to the suction side of the water pump and to the cover plate of the resistor.
4. Select location so that resistor will be grounded and inlet line will be less than 18 inches in length.
5. Open shut-off valve; start engine and check for leaks.
6. After a few minutes, check resistor head temperature to see if coolant is circulating. If resistor head is cold, disconnect outlet line to bleed off air. Recheck for circulation.

THERMOSTAT

C, J, H, NH, NT Engines

1. Disconnect hose from water outlet connection on thermostat housing.
2. Disconnect and remove air compressor water lines (if equipped).
3. Disconnect turbocharger water outlet line (if used) at housing.
4. Remove capscrews holding thermostat housing to cylinder head water outlet connection and separate the two units.
5. On turbocharger engines, lift housing from water by-pass coupling.
6. Remove thermostat and discard gasket.

Installation

1. Install new or tested thermostat, using new gasket. On turbocharged engines, use new rubber O-ring on water by-pass coupling.
2. Install thermostat with "V" notch at top to vent as much air as possible. *Failure to do so may result in an air lock and incomplete coolant circulation.*
3. Install capscrews and washers.
4. Connect air compressor water lines (if equipped). Connect water outlet hose and tighten clamp.
5. After filling cooling system, open drain cock at top of thermostat housing to bleed out air.

V6-200, V8-265 Engines

1. Drain cooling system.
2. Disconnect hose from water outlet on thermostat housing cover.
3. Unfasten thermostat cover from housing.
4. Lift off cover and thermostat, and

remove gasket and thermostat from cover.

Installation

1. Install new or tested thermostat in cover. With new gasket, position cover to housing and secure with capscrews and lockwashers.
2. Fill cooling system.

V8-350, VT8-430 Engines

1. These engines are equipped with two thermostats located in housings mounted at front end of each cylinder head. To remove, proceed as follows:
2. Drain cooling system, loosen hose clamps and disconnect hoses from water outlet connections on each thermostat housing.
3. Unfasten thermostat covers from cross-over pipe; remove cross-over pipe and gaskets.
4. Loosen hose clamps securing water by-pass pipe to water pump.
5. Unfasten left-bank thermostat housing cover from by-pass pipe, and lift off by-pass pipe and gasket.
6. Unfasten and lift off thermostat housing covers.
7. Lift off both housings and thermostats, and remove thermostats from housings.

Installation

1. If thermostat housing seals were discarded, install new seal, lip first, into each housing. Press seal in until it is flush with housing. *Reversing lip of seal will allow leakage between by-pass and main coolant flow. Do not press seal into by-pass passage.*
2. Insert thermostats in housing counterbore and through seals.
3. Position and secure new gaskets, thermostat housings and covers on cylinder head pads.
